31. *Geranium Bohemicum*; *Bohemian Crane's Bill*. Petals emarginate; arils rough with hairs; cotyledons trifid, with the middle cleft truncate; stems many, branched; leaves five-lobed, crenate, on long footstalks, and mostly opposite; flowers on long, slender, axillary peduncles; co-

rolla of a fine blue colour. It flowers from June to August. —Native of Bohemia.

32. *Geranium Robertianum*; *Stinking Crane's Bill*, or *Herb Robert*. Leaves quinate and ternate, gashed; calices ten-angled; stems spreading, branched, blood-red, hairy, particularly in young plants; stipules four at each joint, two on each side; peduncles very long; pedicels short; calicine leaflets ovate-lanceolate, nerved, hairy, ending in a long awn, the ten-angled formed by the first and third outer leaves, being each folded into three keel-like angles, the second and fifth each into one, and the fourth into two, the angles become more evident as the seeds ripen; petals rose-coloured, varying to white, spreading, and equal; the lamina somewhat heart-shaped; the claw long and linear, the middle part of it prominent, grooved, and spreading into three whitish nerves; the whole is beset with pellucid hairs, but becomes smoother as the plant grows older; it is commonly red at the joints, and the whole plant is frequently red. It has a disagreeable rank smell when bruised. In the variety of this plant, which occurs near Swarming in Dorsetshire, and on the shore of Selsey island, the whole plant is shining; the leaves smaller, and more deeply divided. A strong decoction of this plant has been found to afford relief in the stone and gravel; and is also given to cattle when they make bloody water, or have the bloody flux. This plant, says Meyrick, is an excellent vulnerary or wound herb, whether used externally or internally. An ointment made of the green leaves and hog's lard, is good for sore breasts, and has been found serviceable to anoint scrofulous or cancerous swellings with. Cattle have certainly been cured of what the farmers call the black water, and of the bloody flux, by a decoction of this herb, after all other medicines have proved ineffectual; and there is little doubt but its effects on the human body would be equally salutary in similar circumstances. The whole plant should be gathered, root and all, and dried for use; it is a most excellent astringent; scarcely any plant is in that respect equal to it: it may be given dried or powdered, or in decoction. It stops overflows of the menses, bloody stools, and all other hæmorrhages. It is to be observed, that nature seems to have set her stamp upon several herbs, which have the virtue to stop bleedings; this and the tutsan, the two best remedies the fields afford for outward and inward bleedings, become all over as red as blood at a certain season. The name *stock-bill* is set down in Dr. Withering's arrangements; which is probably a corruption of *storkbill*.—Native of all parts of Europe, in woods, under hedges, in hollow trees, on walls, and the roofs of houses, among rubbish, and in stony places, flowering from April through the whole of the summer.

Geranium. See *Erodium*, and *Pelargonium*.

Gerardia; (so called, in honour of John Gerarde, the celebrated English botanist,) a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, upright, sharp, permanent. *Corolla*: one-petalled, ringent; tube round, longer than the calix; upper lip upright, blunt, flat, broader, emarginate; lower lip reflex, three-parted; divisions lateral, emarginate, middle shorter, two-parted. *Stamina*: filamenta four, scarcely the length of the tube, two a little shorter; antheræ small. *Pistil*: germen ovate, small; style simple, short; stigma blunt. *Pericarp*: capsule ovate, two-celled, two-valved, gaping at the base; partition contrary. *Seeds*: ovate, solitary. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Corolla*: two-lipped; lower lip three-parted; the lobes emarginate; the middle segment two-parted; capsule two-celled, gaping.—The species are,

1. *Gerardia Tuberosa*; *Tuberous Gerardia*. Leaves sub-ovate, tomentose, repand, the length of the stalk; root-leaves as on the spike; bractes imbricate, one-flowered; border of the corolla wheel-shaped.—Native of South America.

2. *Gerardia Japonica*; *Japanese Gerardia*. Leaves ovate, gash-pinnatifid, petioled; stalk simple; flowers axillary, peduncled, solitary; peduncles many times shorter than the leaves; corolla purplish; stalk villose.—Native of Japan.

3. *Gerardia Delphinifolia*; *Larkspur-leaved Gerardia*. Leaves linear, pinnatifid; stalk somewhat branched; stem a foot high, obtusely four-cornered, upright, even, with few alternate branches; flowers axillary, from the middle to the top of the stem, opposite, directed one way, on very short peduncles; corollas oblong, with a gaping mouth, and a five-lobed rounded border, the two upper lobes shorter.—Native of the East Indies.

4. *Gerardia Scabra*; *Rough Gerardia*. Hispid, scabrous; leaves oblong, pinnatifid.—Native of the Cape of Good Hope.

5. *Gerardia Purpurea*; *Purple Gerardia*. Leaves linear; root annual; stalks a foot high, filiform, either very simple, or brachiate, smooth; flowers opposite, on one-flowered filiform peduncles, or else sessile; calices smooth, small, bell-shaped, five-toothed; corollas very deep purple, either wheel-shaped or bell-shaped, or tubular.—Native of North America.

6. *Gerardia Tubulosa*; *Long-tubed Gerardia*. Smooth; leaves linear, entire, sharp; tube of the flower longer than the calix.—Native of the Cape of Good Hope.

7. *Gerardia Flava*; *Yellow Gerardia*. Leaves lanceolate, pinnate-toothed; stalk extremely simple; stalk a foot high or more; spike terminating, lax, consisting of opposite large yellow flowers: there is no fifth stamen.—Native of North America.

8. *Gerardia Pedicularia*. Leaves oblong, doubly-serrate; stalk panicled; calices crenate; corollas pubescent on the outside, oblong, patulous.—Native of North America.

9. *Gerardia Glutinosa*. Leaves ovate-serrate; bractes linear, hispid; stem roundish, upright, with short branches; racemes terminating, solitary, composed of opposite flowers, on very short peduncles; calices five-parted, sharp, the uppermost division largest; a filiform bracte or two, of the same length with the calix, is close to it, hispid, like that with glutinous hairs.—Native of China.

10. *Gerardia Nigrina*. Scabrous; leaves lanceolate, serrate at bottom; stalk four-cornered. This was formerly made a distinct genus by Linneus, under the name of *nigrina*, but he was afterwards of opinion that it could not be separated from the *Gerardias*.—Native of the Cape of Good Hope.

Germander. See *Teucrium*.

Geropogon; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common, simple, many-leaved; leaflets lanceolate-subulate, keeled, upright, longer than the corolla. *Corolla*: compound, subimbricate, uniform; corollules hermaphrodite, outer as many as there are leaflets in the calix, inner fewer, shorter, proper, one-petalled, ligulate, truncate, five-toothed. *Stamina*: filamenta five, very short; antheræ cylindric, tubular. *Pistil*: germen oblong; style filiform, the same length with the stamina; stigmas two, bowed back, filiform. *Pericarp*: none; calix oblong, upright, gaping. *Seeds*: of the ray subulate, the same length with the calix; down with five patulous awns; of the disk subulate, shorter; down feathered. *Receptacle*: with bristle-shaped chaffs. *Observe*: there is a species with a calicled calix. ESSENTIAL CHARACTER. *Calix*: simple. *Receptacle*: with bristle-shaped chaffs. *Seeds*: of the disk with a feathered down; of the ray, with

five awns. For the propagation and culture of this species, see *Tragopogon*.—The species are,

1. *Geropogon Glabrum*; *Smooth Geropogon*, or *Old Man's Beard*. Leaves smooth. It has an upright stalk more than a foot high, with long grass-like leaves; the stalk branches at top into two or three divisions, each terminated by one flesh-coloured flower. The whole plant is smooth; calix usually seven-leaved.—It is an annual plant, and a native of Italy.

2. *Geropogon Hirsutum*; *Rough Geropogon*. Leaves hairy; stalks upright, a foot high. It seldom divides into branches, but is terminated by one flower: annual.—Native of Italy.

3. *Geropogon Caliculatum*; *Perennial Geropogon*. Calices calicled; root perennial; stems several, branched; flowers terminating, nodding before they open; leaves sub-linear, acuminate, the lowest stem-leaves and the root-leaves channelled beneath, and hairy on both sides, the upper ones flat, and a little hirsute only on the back; stems ascending, round, a foot and a half high, villose, and leafy; corolla yellow on both sides; receptacle naked.—It flowers in June, and is a native of Italy.

Gesneria; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, superior, five-cleft, sharp, permanent. *Corolla*: one-petalled, incurved, and recurved; tube thickish, with a contracted neck and funnel-form throat; border five-cleft, blunt; upper divisions concave, three lower flat, spreading. *Stamina*: filamenta four, shorter than the corolla. *Antherae* simple. *Pistil*: germen inferior, flattened; style filiform, the same in situation and length with the stamina; stigma capitate. *Pericarp*: capsule roundish, and crowned with the patulous calix, subbilocular; partition in the middle, longitudinally interrupted. *Seeds*: extremely numerous and very small; receptacles on each side fastened to the partition. *Observe*: if the capsule be cut transversely near the top, it appears to be one-celled; if through the middle, two-celled. ESSENTIAL CHARACTER. *Calix*: five-cleft, sitting on the germen. *Corolla*: incurved and recurved. *Capsule*: inferior, two-celled.—The species are,

1. *Gesneria Humilis*; *Low Gesneria*. Leaves lanceolate, serrate, sessile; peduncles branched, many-flowered; root diffused, creeping; stem branched, naked at bottom; peduncles branched, three-flowered.—Native of Carthage, in New Spain. This, like all the plants of this genus, is propagated by seeds, which must be procured from the country where they naturally grow. They should be brought over in their capsules, for as they are very small and light, when they are separated from the partition to which they adhere, they soon lose their vegetative power. These seeds should be sown in pots filled with light earth, and plunged into a hot-bed of tanner's bark as soon as they arrive, for they sometimes lie long in the ground; those which Mr. Miller sowed in autumn, came up in the following spring; therefore when they happen to arrive here at that season, the pots in which the seeds are sown should be plunged into the tan-bed in the stove, and during the winter the earth should be now and then gently watered, to prevent it from becoming too dry, but at the same time it must not be made too moist. In the spring, the pots should be removed out of the stove, and plunged into a fresh hot-bed, which will bring up the plants soon after. When these are fit to remove, they should be each planted in a separate pot, and plunged into a good hot-bed of tan, observing to shade them till they have taken new root, and afterwards treat them in the same way as other plants from the same countries. In autumn they must be plunged into the tan-bed in the stove, where during the winter they should have but little water given to them,

for if they receive much wet it will destroy them: in this stove the plants must constantly remain, for they will not thrive when taken out of the tan. In the summer, free air should always be admitted to them during warm weather, and they should at that time also be frequently refreshed with water, but never in too great a quantity. As the plants advance in growth they will require larger pots, but there must be care taken not to overpot them, for they will not thrive in large pots. With this management the plants will flower in the second year, and may be continued three or four years; but they are not of long duration in their native country.

2. *Gesneria Acaulis*; *Stemless Gesneria*. Leaves lanceolate-ovate, serrate, subpetioled, crowded at the end; peduncles three-flowered, shorter than the leaf; stem round, woody, having a clay-coloured bark, with some furrows in it; rising three or four inches high, having at the top very many oblong leaves, standing very thick, without any order, on foot-stalks a quarter of an inch in length, covered with a reddish wool-like moss. They are seven inches long, and an inch and a half broad near the farther end, whence they narrow to a point, and also grow gradually narrower to the foot-stalk; from the axils come out small peduncles, branched, sustaining scarlet flowers an inch long, which are followed by a short, fungous, cornered seed-vessel, having no distinct cells, containing many small, oblong, yellowish seeds. Browne calls it *small-tufted Gesneria*, with scarlet flowers; and observes, that the stem is always simple, creeping along the rocks, and bearing a pretty large tuft of leaves at each extremity, with single flowers springing from each axil.—Native of Jamaica. For its propagation and culture, see the first species.

3. *Gesneria Tomentosa*; *Woolly Gesneria*. Leaves ovate-lanceolate, crenate, hirsute; peduncles lateral, very long, corymbiferous. This rises with a shrubby stalk to the height of six or seven feet, dividing into two or three irregular branches, covered with a russet wool; corolla irregular, sub-campanulate, gibbous at the base and under the limb; the two upper segments approximate, so as to form one as it were that is bifid, arched in the middle, spotted on the inside with yellow and dark purple; the three lateral ones are spreading, ovate-acute, the lowest ventricose underneath; the tube is spotted within; the two interior filamenta are longer than the two others, and are bowed in towards the pistil; anthera convex. This plant bears some affinity to the saxifrages, in the situation of these receptacles, and in the opening of the capsule. Browne calls it the *hairy erect Gesneria*, with open flowers.—Native of Jamaica. For its propagation and culture, see the first species.

4. *Gesneria Craniolaria*. Leaves wedge-shaped, oblong, tooth-laciniate; peduncles terminating; corollas bell-shaped. It rises with a shrubby stalk to the height of ten or twelve feet, dividing upwards into a few branches, which are garnished with spear-shaped leaves, cut on their edges, these are soft and hairy; the flowers are produced from the side of the branches, growing several together on the same foot-stalk, they are shaped like those of the foxglove, of a greenish yellow colour, with brown spots on the inside; the flowers have a swelling tube, which is recurved; and the brim is slightly divided into five unequal segments. They appear in July, but are not succeeded by seeds in England. This sort grows naturally at the Havannah, and in some other islands of America.

5. *Gesneria Grandis*. Leaves broad-lanceolate, very long, toothletted, rough-haired above, rugged beneath; peduncles terminating; stem arborescent.—Native of Jamaica.

6. *Gesneria Scabra*. Leaves ovate-lanceolate, serrate, rugged; peduncles axillary; corollas cylindric, recurved. —This is a shrubby plant, and a native of Jamaica.

7. *Gesneria Corymbosa*. Leaves ovate, acute, serrate, scarious, sharp; peduncles many-parted; flowers in corymbs, shrubby. —Native of Jamaica. See the first species.

8. *Gesneria Exserta*. Leaves ovate, lanceolate, crenate, smooth; peduncles three-flowered; genitals twice the length of the corolla; capsules ovate, shrubby. —Native of Jamaica.

9. *Gesneria Calicina*. Leaves lanceolate, ovate, acuminate, serrate, smooth; peduncles three-flowered; genitals longer than the corolla; calices bell-shaped; capsule cylindric. It is a shrubby plant, and a native of the West Indies. See the first species.

10. *Gesneria Ventricosa*. Leaves elliptic, acuminate, crenate, smooth; peduncles four-flowered or thereabouts; segments of the calix awl-shaped, elongated; corollas ventricose. This also is a shrubby plant, and a native of Jamaica. See the first species.

11. *Gesneria Pulchella*. Herbaceous: leaves ternate, ovate, acute, serrate, villose; peduncles axillary, one-flowered. Brown describes this as having a slender even stem, seldom rising above ten or fourteen inches in height, and throwing out a beautiful single reddish flower from the axil of each of the upper leaves; filaments longer than the corolla; and somewhat twisted as they rise. —Native of Jamaica. The eleventh sort deserves to be cultivated in the flower-gardens of America. It thrives best in a cool gravelly soil, well furnished with moisture, and intermixed with rich mould.

12. *Gesneria Pumila*. Stemless: leaves ovate, wedge-shaped, crenate, subsessile; peduncles subbiflorous, shorter than the leaves. —Native of Jamaica. See the first species.

Gethyllis; a genus of the class Hexandria, order Monogynia. —GENERIC CHARACTER. *Calix*: none, unless a sheath obliquely truncate. *Corolla*: one-petalled, superior; tube long, filiform, radical; border expanding, flat, six-parted; divisions oblong. *Stamina*: filaments six, inserted into the mouth of the tube, shorter than the border, usually divided; antheræ linear, spirally bent in. *Pistil*: germen inferior; style simple, longer than the stamina; stigma capitate. *Pericarp*: berry club-shaped, blunt, radical, (sessile in the bulb itself, and proceeding from it,) somewhat fleshy, one-celled. *Seeds*: nestling one upon another, in three rows, globular, smooth. *Observe*. In some flowers, particularly those of the second species, the filaments are divided above the base, with as many antheræ; but two antheræ are seldom seen on a single filamentum; so that the same flower may have eight, ten, or more antheræ. ESSENTIAL CHARACTER. *Calix*: none. *Corolla*: six-parted; berry club-shaped, radical, one-celled. All the plants of this genus have the habit or air of *colchicum*, but are sufficiently distinguished from it, by having a monopetalous corolla, and a berry for a fruit. There is but one flower on a naked stalk; and the fruit has a grateful odour, with a pleasant taste. —The species are,

1. *Gethyllis Villosa*; *Hairy Gethyllis*. Leaves linear, filiform, spiral, villose; segments of the corolla ovate-oblong. —Native of the Cape of Good Hope.

2. *Gethyllis Ciliaris*; *Fringed Gethyllis*. Leaves linear, spiral, ciliate; segments of the corolla ovate-oblong. —Native of the Cape of Good Hope.

3. *Gethyllis Spiralis*; *Spiral Gethyllis*. Leaves linear, spiral, smooth; segments of the corolla oblong. It has been long known in Europe. —Native of the Cape of Good Hope.

4. *Gethyllis Lanceolata*; *Lanceolate Gethyllis*. Leaves

lanceolate, flat; segments of the corolla lanceolate. —Native of the Cape of Good Hope.

Geum; a genus of the class Icosandria, order Polygamia. —GENERIC CHARACTER. *Calix*: perianth one-leaved, ten-cleft, uprightish; segments alternately very small, sharp. *Corolla*: petals five, rounded; claws the length of the calix, narrow, inserted into the calix. *Stamina*: filaments numerous, subulate, length of the calix, into which they are inserted; antheræ short, broadish, blunt. *Pistil*: germina numerous, collected into a head; styles inserted into the side of the germen, hairy, long; stigmas simple. *Pericarp*: none; common receptacle of the seeds oblong, hirsute, placed on the reflex calix. *Seeds*: numerous, compressed, hispid, awned, with a long style. ESSENTIAL CHARACTER. *Calix*: ten-cleft. *Petals*: five. *Seeds*: with a kneed awn. This genus consists of perennial herbaceous plants. The leaves are usually unequally pinnate, with the terminating leaflet larger than the rest. The stipules fastened to the petiole. The peduncles terminating or axillary, supporting few flowers, sometimes only one. —The species are,

1. *Geum Virginianum*; *American Avens*. Flowers upright, awns hooked, naked; stem-leaves ternate, the upper ones lanceolate; petals shorter than the calix; stem a foot and a half or two feet high, branching at top into small peduncles, each terminated by a small white flower. It flowers in July and August, and is a native of North America.

2. *Geum Strictum*; *Upright Avens*. Flowers upright; awns hooked, naked; stem-leaves pinnate; leaflets and stipules gash-cleft; petals longer than the calix; stems upright, round, a foot and a half high and more; most of the branchlets ending in one-flowered peduncles; root-leaves pinnate, and petioled, with the outmost leaflet very large, rounded and lobed; the side ones ovate, differing much in size, all sessile, and unequally serrate; sometimes the extreme leaflet is trifid palmate; sometimes, but more rarely, all the leaflets are deeply gashed; stem-leaflets lanceolate, and acute. It flowers in May and June. —Native of North America.

3. *Geum Urbanum*; *Common Avens*, or *Herb Bennet*. Flowers upright; awn hooked, naked; stem-leaves ternate; root-leaves lyrate-pinnate; stalks from one to two feet high, nearly upright, somewhat flexuose, slightly angular, hairy, branched at top; peduncles single, nearly upright, round, somewhat hairy, supporting one flower; corolla small, yellow, with very short claws; filaments yellowish, at first bent in, afterwards upright, half as long as the larger segments of the calix; antheræ roundish, yellow, turning brown, having hairs about the edge visible only in a glass; germina hairy; styles smooth, purple, fixed to the top of the germen. The roots have a mildly astringent aromatic taste, somewhat like that of cloves, whence this plant has the name of *caryophyllata*. They should be gathered in dry warm situations, for in shady moist places they have little virtue. Gathered in the spring, and put into fresh ale, they communicate a pleasant flavour, and prevent it from turning sour. Infused in wine, it is esteemed to be a good stomachic; but in water, Haller declares it to have been attended with bad effects, producing delirium, when given to those labouring under malignant fevers. The roots chewed in the mouth are said to relieve an offensive breath. Meyrick describes it to be of a mild, austere, aromatic nature, perfectly adapted to strengthen the head and stomach. A drachm of the powder taken in a glass of wine dissolves and disperses inward congealed blood, occasioned by falls and bruises: it is also efficacious in the bloody flux, and other profuse purgings and spittings of blood. Boiled in water, in the proportion of an ounce to a pint and a half, until one-third of the fluid be

wasted, or, which is better still, infused in half a pint of red port for the space of twelve hours, and the whole quantity taken at the coming on of an ague-fit, has frequently been known to cure that disorder. Hill calls it a cordial and sudorific, and says that it is good in nervous complaints, and that he has known it alone to have cured intermittent fevers, even where the bark has been unsuccessful. This, like all the other plants of the genus, may be propagated by seeds, which should be sown in autumn; for when they are sown in the spring, they do not grow the same year.

4. *Geum Japonicum*; *Flowers upright*; fruits hirsute; awns naked; leaves with three lobes or more; stalk round, flexuose, upright, hirsute, a foot high or more, sometimes, but seldom, a little branched at top; branches alternate, very short, somewhat tomentose; flowers terminating the stem and branches, solitary; seeds ovate, rough, with gray hairs; awns subulate, hooked, reflex, smooth.—Native of Japan.

5. *Geum Rivale*; *Water Avena*. Flowers nodding; awns hooked, villose; petals retuse, roundish, wedge-shaped; leaves pinnate; root creeping, reddish, astringent, aromatic, smelling like cloves; stem a foot high, upright, round, and branched, bending at top, but becoming erect as the fruit ripens; peduncles purplish, hirsute, with hairs terminating in a red globule, becoming less bent as the seeds ripen. It flowers from the end of May till autumn, and varies with double flowers, which frequently become double and proliferous. The powdered root is beneficial in diarrhoeas and hæmorrhages, and is much used by the Canadians in the cure of tertian agues. It will cure malt-liquor of its ropiness.—Native of most countries in Europe, where it is found in moist pastures and woods, and indicates, according to Linneus, a barren soil unfit for corn. It is common also in the Levant, and in North America. With us it is more common in the north, as on the water of Leith near Edinburgh, and other parts of Scotland on moorish grounds. It has been observed near Settle and Ingleton in Yorkshire, in Lancashire, and generally by the sides of rivers, and on mountains in many parts of the northern counties. Found also near Chevely and Wood Ditton in Cambridgeshire, in Wolverton wood near Lynn, at Marham near Swaffham, and near Norwich in Norfolk, in a bog near Sudbury in Suffolk, near Aston in Warwickshire, and upon Snowden, and various other parts of Wales.

6. *Geum Hybridum*; *Mule Avena*. Flower nodding; calix leafy, longer than the polypetalous corolla. The lower leaves are interruptedly pinnate, with three pair of leaflets, besides the smaller ones, and that at the end, which is very large; calix duskier purple, tinged with green; corolla yellow, only tinged with purple at the edge, about the same length with the calix, having sometimes more petals than five.

7. *Geum Montanum*; *Mountain Avena*. Stem one-flowered; awns straight, villose; leaves pinnate, hairy, outmost leaflet very large and roundish, the lower ones gradually smaller; root-leaves in a tuft, on petioles of different lengths; these are hairy, and have several pairs of leaflets on them, the lowest very small, the succeeding ones gradually larger, and the pair immediately under the great terminating leaflet much bigger than any of the rest; the extreme leaflet is two or three inches in length and breadth, obscurely lobed, gash-serrate, and veined; flowers large, solitary, spreading, upright; calix wide, hairy, green. The small mountain avenu is made a distinct species by Mr. Miller, who says that it is a very low plant, with flower-stalks about three inches long, bending on one side, each terminated by one bright yellow flower. In its native places it flowers in June and July, and

in our gardens from May to September.—Native of the mountains of Switzerland, Austria, Silesia, and Dauphiny.

8. *Geum Potentilloides*; *Siberian Avena*. Stem one or two-flowered; awns straight, naked; calices of the fruit upright; leaves pinnate-toothed. On account of the ripe calix being bell-shaped, the corolla yellow and five-petalled, the receptacle elongated, the awns naked and jointed, this approaches nearer to a *geum* than a *dryas*: receptacle cylindrical, slender, excavated, naked, a little shorter than the calix; seeds numerous, obovate, gibbous on one side, thence comprised into a straight keel, shagreened on all sides with raised dots, of a brown ferruginous colour; awn straight like a needle. It flowers in June.—Native of Siberia.

9. *Geum Reptans*; *Creeping Avena*. Stems one-flowered; awns straight, villose; leaves pinnate, gashed, hairy; runners creeping; root large and woody; flower much larger than the seventh species; calix green, with the segments often reddish; petals yellow, emarginate, marked with lines much larger than the calix; the whole corolla sometimes two inches in diameter. It flowers in June and July, and is a native of Switzerland, Austria, Silesia, Savoy, and Piedmont.

Ghinia; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, permanent; mouth expanded, five-toothed, acuminate. *Corolla*: one-petalled, irregular; tube long, narrow; border two-lipped; upper lip largest, roundish, concave, ascending; lower three-parted; segments roundish; the middle one largest, bent down, emarginate. *Stamina*: filamenta four, inserted into the tube above the base, two longer than the others; antheræ with oblong cells, one at the end, fertile in the longer filamenta, barren in the shorter, the other inserted towards the middle of the filamentum, in the shape of a scale. *Pistil*: germen roundish; style the length of the tube; stigma four-lobed. *Pericarp*: drupe turbinate, angular, longer than the calix, which is permanent. *Seed*: nut angular, four or five-celled, with one seed in each cell, according to Swartz, four-cornered, four spines at the end, four-celled, with solitary kernels. ESSENTIAL CHARACTER. *Calix*: five-toothed; teeth acuminate. *Corolla*: two-lipped. *Stamina*: four, with two barren antheræ at the end of the shorter filamenta. *Pericarp*: a drupe containing a four or five-celled nut, with a seed in each cell. Swartz calls it a fleshy four-celled nut.—The species are,

1. *Ghinia Spinosa*. Fruits four-spined; stem slender, woody, branching, nearly three feet high; leaves oval, sharply indented, light green, on short footstalks; flowers distant, sessile, in a loose spike, on slender, naked, axillary peduncles, six or seven inches in length; corollas small, bright blue; seeds two, terminated by short awns, and enclosed in the calix.—Annual, and a native of the West Indies.

2. *Ghinia Mutica*. Fruits without spines; stems strong, straight, and a little woody; leaves rounded or subovate, deeply toothed, having short hairs on both surfaces; petiole three or four lines in length; spikes axillary, opposite; flowers solitary, few, alternate, pedicelled, with a small linear bracte at the base of each pedicel; corolla blue.—Native of Guiana, and the island of Cayenne.

Gilliflower. See *Dianthus*.

Gilliflower, *Stock*. See *Cheiranthus*.

Gilliflower, *Queen's*, or *Dame's Violet*. See *Hesperis*.

Ginannia; a genus of the class Enneandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth double; outer one-leaved, bifid, acute; inner one-leaved, cup-shaped, four or five-cleft; segments oval, concave, obtuse, spreading, one larger than the rest. *Corolla*: petals three, oblong, obtuse, fringed, spreading, inserted into the larger segment

of the calix at the base. *Stamina*: filamenta nine, filiform, flexuose, longer than the corolla, inserted into the mouth of the calix; antheræ paralleliped, versatile. *Pistil*: germen oblong, compressed at the bottom of the calix, affixed to a pedicel, with a membranaceous wing at top; style filiform, flexuose, the length of the stamina; stigma obtuse. *Pericarp*: legume long, straight, one-celled, two-valved, pedicelled. *Seeds*: very many, oval, flattened, smooth. **ESSENTIAL CHARACTER.** *Calix*: double, both one-leafed. *Petals*: three, fringed, spreading. *Germen*: pedicelled, with a membranaceous wing at top.—The only known species is,

1. *Ginannia Guianensis*. This is a shrub, growing to the height of fifteen feet, beginning to be branched at one or two feet from the ground; leaves alternate, entire, smooth, ovate-oblong, acuminate, subsessile, the largest six inches long, and two inches and a half wide; stipules minute, in pairs at the base of the petioles; flowers terminating, three or four together, on a short peduncle, on which are four or five soft green scales or bractes.—Native of the forests of Guiana, flowering in February, and fruiting in May.

Ginger. See *Amomum*.

Ginko; a genus hitherto imperfectly described, the only known species of which is,

1. *Ginko Biloba*, or *Maidenhair Tree*. This tree grows to a prodigious size, with a trunk frequently as thick as the largest oak; the branches are alternate, and spreading. Of the fructification, we yet know very little with certainty. The flowers are male and female, separate, probably on different trees. They come out in April, before the leaves, and from the same bud with them, towards the end of the branches, or aments, or catkins, as Kæmpfer describes them, pendent, and longish, abounding in pollen. The fruit grows on a thick fleshy peduncle, an inch in length, and, having figured them single, Kæmpfer describes them as round or oblong, of the size and appearance of a damson or damascene plum, with a warted surface, becoming yellow as the fruit ripens, and a fleshy, juicy, white pulp, adhering very closely to the nut, which resembles that of the pistachia, but is almost double the size, and more of the form of the apricot stone; the shell is woody, thin, brittle, and whitish, and the kernel is white, rather firm, sweet, with a mixture of austerity or bitterness, when raw, but is agreeable when gently roasted on the coals, before the skin is taken off; and in that state, is supposed to help digestion.—Native of Japan and China.

Ginora; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed; tube bell-shaped; border six-cleft; segments lanceolate, spreading, coloured, permanent. *Corolla*: petals six, roundish, spreading, longer than the calix, with long claws inserted into the neck of the calix. *Stamina*: filamenta twelve, subulate, patulous, as long as in the calix, and inserted into it; antheræ kidney-shaped. *Pistil*: germen roundish, flattened; style subulate, the same length with the corolla, permanent; stigma obtuse. *Pericarp*: capsule flattened and roundish, shining, coloured, somewhat four-grooved, four-valved, one-celled, gaping at the tip. *Seeds*: very many, minute; receptacle roundish, large. **ESSENTIAL CHARACTER.** *Calix*: six-cleft. *Petals*: six. *Capsule*: one-celled, four-valved, coloured, containing many seeds.—The only known species is,

1. *Ginora Americana*. It grows upright, to the height of three or four feet, and divides into smooth branches, round, except that they are compressed at the origin of the twigs and leaves, all woody; leaves lanceolate, acute, quite entire, smooth, spreading, an inch and a half long, on very short

petioles; peduncles slender, spreading, solitary, an inch in length; flowers handsome, almost an inch in diameter, without any scent; calix red; corolla blue; capsule dark red, outwardly resembling a berry. It is an elegant shrub, with the appearance of myrtle.—Native of Cuba, by river sides, where it is called *rosa del rio*, or *river rose*.

Ginseng. See *Panax*.

Gisekia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate, concave, blunt, scarioso at the edge, permanent. *Corolla*: none. *Stamina*: filamenta five, subulate, ovate at the base, short; antheræ roundish. *Pistil*: germen superior, roundish, retuse, five-parted; styles short, bowed back; stigmas blunt. *Pericarp*: capsules five, roundish, somewhat flattened, scabrous, blunt, approximating. *Seeds*: solitary, ovate, smooth. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: none. *Capsules*: five, approximating, roundish, one-seeded.—The only known species is,

1. *Gisekia Pharnacioides*; *Trailing Gisekia*. Stalks herbaceous, decumbent, smooth, round, scored with a line on the upper side, a foot long, with remote joints; branches of the base alternate; leaves opposite, petioled, elliptic-lanceolate, quite entire, blunt, smooth, and even, spreading; peduncles axillary, solitary, round, naked; umbel simple, many-flowered; flowers green on the outside, white within, hanging down, except on the day of flowering. It is an annual plant, flowering here in June, and a native of the East Indies.

Githago. See *Agrostemma*.

Glabraria; a genus of the class Polyadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, tubular, five-cleft, shorter by half than the corolla. *Corolla*: petals five, lanceolate, blunt, equal; nectary surrounding the germen, with subulate, upright, coloured bristles, the length of the calix. *Stamina*: filamenta thirty, capillary, interposed between the nectaries, in sixes, connected at the base, the same length with the calix; antheræ kidney-shaped. *Pistil*: germen subglobose; style filiform, the length of the stamina; stigma simple. *Pericarp*: drupe juiceless, one-celled. *Seed*: a bony oval nucleus. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Petals*: five. *Nectary*: composed of bristles, the length of the calix. *Stamina*: thirty, always in sixes. *Pericarp*: a drupe.—The only known species is,

1. *Glabraria Tersa*. A large tree, resembling *laurus camphora*, or the *camphor-tree*. Leaves alternate, petioled, ovate, lanceolate, quite entire, smooth, acuminate, submentose underneath, even nevertheless, and glaucous; flowers white, in little axillary balls, forming a sort of raceme, leafless, and much shorter than the leaves. The wood of this tree is very light and pale-coloured, not being liable to the rot, or to the attacks of insects: it is much used in the East Indies, for house and ship-building.

Gladiolus: a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: a spathe two-valved, inferior, shorter than the corolla; valves oblong, permanent, the outer one larger, inclosing the inner. *Corolla*: one-petalled, superior; tube cylindric, bent; border somewhat bell-shaped, six-parted; segments oblong, from erect patulous, the uppermost and lowest lateral, either without or within. *Stamina*: filamenta three, inserted into the orifice of the tube, filiform, shorter than the corolla; antheræ ovate, incumbent. *Pistil*: germen inferior, triangular; style filiform; stigmas three, rolled back, and spreading, blunt, villous. *Pericarp*: capsule ovate, three-cornered, blunt, three-celled, three-valved. *Seeds*: very many, smooth.

Gärtner observes, that *antholyza* may be very well placed in this genus. **ESSENTIAL CHARACTER.** *Corolla*: six-parted, irregular, unequal. *Stigmas*: three.—The species are,

1. *Gladiolus Communis*; *Common Corn Flag*. Leaves sword-shaped; flowers distant; root round, compressed, yellowish, covered with a brown furrowed skin; hence spring two sword-shaped leaves, embracing each other at the base; and between them rises the flower-stalk, growing nearly two feet high, having one or two narrow leaves embracing it like a sheath, and terminated by five or six purple flowers, one above another at some distance, ranged on the same side of the stalk. Mr. Miller makes three species of this. 1. That above described, with the flowers disposed on one side of the stalk, varying with white and flesh-coloured flowers, which Gerarde calls the Italian corn-flag: 2. the Italian, or *utrinque floridus* of *Caspar Bauhin*, with flowers on each side the stalk, of which, he says, there is also a variety with white flowers, called by Gerarde and Parkinson, the French corn-flag: 3. the great corn-flag of Byzantium, which has larger roots, but of the same form; the leaves are also much broader and larger, with deeper channels. The flower-stalks rise higher; the flowers are much larger, of a deeper red colour, and the sheaths are longer. It makes a fine appearance when in flower, and is worthy of a place in every good garden, especially as the roots do not increase so rapidly as to become troublesome. Parkinson, besides the French, Italian, and Byzantine corn-flags, has three varieties, the blush, white, and small purple. The first requires no care; for when it is once planted, it will multiply fast enough. The Byzantine flag has latterly supplanted it. This is propagated by offsets, which are sent off from the roots, in the same manner as tulips. The roots may be taken out of the ground at the end of July, when their stalks decay, and may be kept out of the ground till the end of September, or the beginning of October, at which time they should be planted in the borders of the flower-garden, where they will thrive in any situation, and being intermixed with other flowers of the same growth, add much to the variety.

2. *Gladiolus Imbricatus*. Leaves sword-shaped; flowers imbricate; flowers small.—Native of Russia.

3. *Gladiolus Alatus*. Leaves sword-shaped; the side petals very broad; stem a span high, thickish, flexuose between the flowers; upper lip of the corollas sickle-shaped, narrow; side petals or wings of the same length, rhomb-shaped, very broad; lower lip three-parted; the leaflets ovate and equal.—Native of the Cape of Good Hope. This, and all the other Cape sorts, may be increased by offsets, which should be planted in a warm border of kitchen-garden earth; and in winter they should be covered with glasses or mats, to guard them from the frost. A slight shelter has preserved those in pots under a common frame, and even some that were planted in the full ground, when the frost has not been severe. But it has always been remarked, that those plants, which were hardly treated, grew much stronger than those which were placed in a moderate degree of warmth; so that were it is convenient to cover a warm border with glasses in the winter, if these roots be planted under them in the full ground, and only protected from frost, there will be a greater probability of their flowering, than under any other mode of culture. They may also be propagated by seeds, which are often perfected in England: the seeds should be sown at the end of August, in pots filled with light earth, and placed in a shady situation till the middle of September; the pots should then be placed so as to enjoy the sun during the greater part of the day, until October, when they must be

removed under a hot-bed frame, where they may be protected from frost and great rains, but enjoy the free air in mild weather. In the spring, the young plants will appear, and will require a little water once in eight or ten days; but it should be very sparingly given, for too much moisture will rot their delicate bulbs. In May, when the danger of frost is past, the pots should be removed to a sheltered situation, where they may have the morning sun till noon, and, if the season prove dry, be now and then refreshed with water. Towards the latter end of June, the leaves of these plants will decay; the roots should then be taken up, and may be mixed with sand, and kept in a dry room till the end of August, when they should be planted again; and as the roots are small, four or five may be set in each halfpenny pot filled with light earth, and placed where they may have only the forenoon sun till the middle of September, when they should have a warmer situation, and in October should be placed under a hot-bed frame as before, and treated in the same way during the winter. In the spring, they must be placed in the open air till their leaves decay, when they may be again taken out of the ground, and treated in the same manner as before; but as the roots will have grown to a larger size, when they are planted again, they should each have a separate halfpenny pot, because they will not be large enough to flower, and may be treated as old roots.

4. *Gladiolus Tubiflorus*; *Long-tubed Corn Flag*. Leaves linear-lanceolate, villose, somewhat plaited, longer than the scape; tube very long; spathes hirsute; stem round, villose, a finger's length; flowers sessile, mostly on one side; bractes three at the base of each germen, hirsute, acuminate; the outer an inch and a half long; the inner half that length; stigmas somewhat wedge-shaped, villose above. It flowers in June.—Native of the Cape of Good Hope. For its propagation and culture, see the preceding species.

5. *Gladiolus Plicatus*; *Hairy Corn Flag*. Leaves oblong-lanceolate, villose, plaited; tube longer than the spathes; root round, compressed, about the size of the small spring crocus; the skin red; from this arise five or six sword-shaped hairy leaves, from two to four inches long, and one-third of an inch broad, dark green, sitting close at the base, but spreading upwards like the sticks of a fan; between these rises the flower-stalk, six or eight inches in length, naked to the top, terminated by a spike of deep blue flowers; corolla divided to the base into six obtuse parts, equal in size and division. It flowers in May, and the seeds ripen in July; soon after which, the stalk and leaves decay to the root.—Native of the Cape of Good Hope. See the third species.

6. *Gladiolus Strictus*; *Upright Corn Flag*. Leaves linear-lanceolate, villose, plaited; tube equal to the spathe. This varies with a blue corolla; the tube and the base of the segments are very dark purple, and with a pale purple corolla; the tube blue. It flowers in June, and is a native of the Cape of Good Hope. See the third species.

7. *Gladiolus Tristis*; *Square-stalked Corn Flag*. Leaves linear, cross-shaped; corollas bell-shaped. From the root come out two or three narrow leaves, a foot and a half long, having a longitudinal furrow in the middle, and ending in acute points; they are of a deep green, and stand erect. Between these arises a slender taper stalk, about the same length as the leaves, having one or two short acute-pointed leaves on the lower part, embracing the stalk at their base; flowers alternate, distant; tube of the corolla curved downwards, not so long as in the other sorts. It flowers at the end of May, and the seeds ripen about six weeks after. Linneus gave the name *tristis* to this species, from the

gloomy colour of its flowers. They are very frequently of a pale yellow or sulphur-colour, as above described, shaded in particular parts with very fine pencillings, especially on the under side; but they vary much with different shades of white and green, yellow, flesh-coloured, blue, purple, and violet. Thunberg has distinguished sixteen of these varieties. It is commonly said to produce only two flowers on a stem; but there are frequently more. They generally emit a most fragrant odour, when they expand.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

8. *Gladiolus Carinatus*; *Spotted-stalked Corn Flag*. Leaves linear, keeled on both sides, smooth; tube of the corolla shorter than the spathes and the borders; stigmas undivided, folded together; stalk a foot and a half high, and round; flowers sweet; tube subcylindric, little more than half an inch in length, whitish; border subcampanulate, subringent; the three upper divisions obovate, oblong, twice as long as the tube, pale violet; the three lower narrower, that in the middle the same length with the three upper ones, yellow below the middle; the side ones shorter, yellow in the middle. It flowers in April and May.—Native of the Cape of Good Hope. See the third species.

9. *Gladiolus Blandus*; *Blush-coloured Corn Flag*. Leaves linear, lanceolate, nerved, smooth; flowers in spikes; the upper segment reflex; stigmas slightly two-lobed; tube of the corolla narrow, compressed, little bent, an inch and a half in length, pale red; filaments white, half the length of the corolla; antheræ oblong, linear, erect, blue; style white, longer than the filaments; stigmas three, patulous, dilated at the top into two lobed laminae, villose at the edge. It flowers in June.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

10. *Gladiolus Undulatus*. Leaves sword-shaped; petals nearly equal, lanceolate, waved; stalk a foot and a half high; flowers alternate in a double row; proper spathes two-leaved; the inner leaf smallest; tube of the corolla long, filiform; the six parts of the border nearly equal, in form of a lily, waved, especially the alternate ones.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

11. *Gladiolus Recurvus*. Leaves sword-shaped; petals nearly equal, lanceolate, bowed back. The flowers are ranged on one side the stalk near the top, and stand pretty far asunder; corolla curved; segments of the border almost equal, ending in blunt points; the lower segments turning downwards, the upper erect, and spreading open; the colour pale blueish, approaching to white; each segment marked with a broad, purple, divided line along the middle. The flowers have an agreeable odour; they appear at the end of May, and the seeds ripen in July.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

12. *Gladiolus Spicatus*. Leaves linear; stem extremely simple; flowers in spikes; scape simple, round, sheathed, erect, a span high; flowers distich, imbricate, blue, about twelve pairs in a spike of an inch long.—Native of the Cape of Good Hope: see the third species.

13. *Gladiolus Alopecuroides*. Leaves linear; spike distich, imbricate. The spike is covered, like that of the plantain, with very numerous small flowers, but in a double row. It varies with the scape, simple and branched, with corollas white and blue.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

14. *Gladiolus Angustus*; *Narrow-leaved Corn Flag*. Leaves linear, smooth; flowers in spikes, distant; the upper seg-

ments of the corolla straight; stigmas spatulate, undivided; scape simple, or but little branched, sheathed, round, striated, smooth, flexuose, erect, a foot high; flowers all on the same side, ascending on one or two spikes a hand in length; rachis angular, flexuose, twisted, smooth; spathes the length of the tube of the corolla, shorter than the branches, green.—Native of the Cape of Good Hope. See the third species.

15. *Gladiolus*; *Yellow Corn Flag*. Leaves lanceolate, sword-shaped, flat; the throat of the upper lip of the corolla has three laminae, shaped like the nail, and placed perpendicularly; bractes acuminate. This differs from the sixteenth species in having the bractes acuminate, the whole corolla intensely yellow, and the leaves a little broader. It flowers in February and March.—Native of the Cape of Good Hope. See the third species.

16. *Gladiolus Securiger*; *Copper-coloured Corn Flag*. Leaves linear, sword-shaped, flat; throat of the upper lip has three laminae, shaped like the nail, and placed perpendicularly; bractes obtuse; stalk roundish, a little shorter than the leaves, sometimes branched; bractes short, ovate, obtuse, sometimes gashed at the tip, membranaceous; corollas pale tawny; tube funnel-shaped, less than an inch in length; segments of the border oblong-ovate, obtuse, sometimes obscurely emarginate, shorter than the tube, the three upper ones having in the chaps a yellow spot, with a border of red round it, and three flat obtuse yellow laminae, a line and half in diameter. It flowers in May.—Native of the Cape of Good Hope. See the third species.

17. *Gladiolus Ramosus*. Stem branched; leaves linear.—Native of the Cape of Good Hope.

18. *Gladiolus Capitatus*. Stem branched; heads peduncled; root tuberous. This is a very large plant, with blue flowers.—Native of the Cape of Good Hope. See the third species.

19. *Gladiolus Crispus*. Leaves lanceolate, crenate, waved; flowers directed the same way; spikes two; tube filiform, long; stem round, with one or two crenate waved leaves on it; glumes obtuse, with a scariose, toothletted, red margin; tube of the corolla twice as long as the border. This is also two feet high, and that only about four inches.—Native of the Cape of Good Hope. See the third species.

20. *Gladiolus Junceus*. Leaves broad-lanceolate; culm branched; flowers directed the same way; style six-parted; stem a hand only in height, filiform, smooth, with one or two patulous branchlets; leaves smooth and even, shorter by half than the stem; flowers alternate, sessile; glumes ovate, entire; corolla violet-coloured, with a filiform tube longer than the border.—Native of the Cape of Good Hope. See the third species.

21. *Gladiolus Anceps*. Leaves sword-shaped, waved; stem branched, ancipital, divaricate; flowers alternate at the tips of the branches; spathes very obtuse, purple at the edge; tube of the corolla three or four times as long as the border.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

22. *Gladiolus Gramineus*. Petals lanceolate, bristle-shaped, acuminate; stem more than a foot high, round, smooth, and even, with few flowering branches; flowers few, at the end of the stem and branches; spathes ovate-acuminate; corolla whitish, with a violet-coloured base, small, without a tube, six-parted.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

23. *Gladiolus Marginatus*. Leaves cartilaginous, margined, smooth, many-nerved; spike lengthened; flowers al-

ternate, nodding; stems the thickness of a goose-quill; spike very long, slightly flexuose between the flowers; spathes distant, the length of the bractes, which are often jagged at the tip; tube of the corolla twice as long as the spathes; segments of the border nearly equal, oblong, elliptic, purple.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

24. *Gladiolus Montanus*. Leaves sword-shaped, nerved, smooth; flowers in spikes; corolla ringent; stem round, leafless; spike oblong, with the flowers rather remote; root-leaves narrow, linear, not above a line in breadth, but nearly the length of the stem, smooth and even; upper lip or helmet of the corolla three-parted; the middle segment arched or bowed in, channelled, linear, ovate at the tip; lateral segments spreading, divaricate.—Native of the Cape of Good Hope. See the third species.

25. *Gladiolus Falcatus*. Stem simple; leaves sickle-shaped; flowers alternate; style trifid; scape compressed, striated; flexuose, smooth, a hand in height; one or two leaves obversely stem-clasping, ovate-lanceolate, sickled, bluntish, entire, striated, smooth; spathes green, obtuse, much shorter than the tube; corolla blue, with a spreading border.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

26. *Gladiolus Flexuosus*. Leaves linear; stem simple, flexuose; flowers in spikes, ringent; tube long; scape round, flexuose; erect, smooth, a foot high; spathes oblong, lanceolate, acuminate, smooth, shorter than the tube of the corolla; spike ovate, four or five-flowered; corolla whitish flesh-colour, with a tube double the length of the spathe, and a ringent border.—Native of the Cape of Good Hope. See the third species.

27. *Gladiolus Longiflorus*; *Long-flowered Corn Flag*. Stem round; tube of the corolla very long; spathes and leaves linear, smooth; scape round, simple, and many-spiked, erect, smooth, a foot high and more; flowers alternate, pale flesh-colour, very many, close; bractes membranaceous, striated, very short.—Native of the Cape of Good Hope. For its propagation and culture, see the third species.

28. *Gladiolus Spathaceus*. Stem branched; flowers in imbricate spikes; spathes membranaceous, awned; leaves plaited; scape sheathed, a span high, terminated by several spikes; flowers whitish, with the tube of the corolla many times longer than the spathes.—Native of the Cape of Good Hope. See the third species.

29. *Gladiolus Setifolius*. Stem branched; corolla ringent; the lowest leaf filiform, setaceous; scape many-spiked, very seldom simple, flexuose, erect, smooth, a hand high, with round erect branches; flowers alternate, white, ringent, with the tube scarcely longer than the spathes.—Native of the Cape of Good Hope. See the third species.

30. *Gladiolus Cardinalis*; *Superb Corn Flag*. Leaves sword-shaped, many-nerved; flowers directed the same way, many on a stem; corolla upright, with a bell-shaped border; flowers fine scarlet, with large white, and somewhat rhomboidal spots on several of the lowermost divisions of the corolla. Strong plants will throw up a stem three or four feet high, dividing at top into several branches. It flowers with us in July and August.—Native of the Cape of Good Hope. See the third species.

Glasswort. See *Salicornia*.

Glastonbury Thorn. See *Mespilus*.

Glaux; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none, unless the corolla be so called. *Corolla*: petal one, five-parted, bell-shaped, upright, permanent; segments obtuse, rolled back.

Stamina: filamenta five, subulate, upright, the length of the corolla. *Antheræ* roundish. *Pistil*: germen ovate; style filiform, the length of the stamina; stigma capitate. *Pericarp*: capsule globular, acuminate, one-celled, five-valved. *Seeds*: five, roundish. *Receptacle*: very large, globular, hollowed for the reception of the seeds. *Observe*: The cover of the flower is perhaps a calix more properly than a corolla. **ESSENTIAL CHARACTER.** *Calix*: one-leafed, bell-shaped. *Corolla*: none. *Capsule*: one-celled, five-valved, five-seeded.—The only known species is,

1. *Glaux Maritima*; *Sea Milkwort*, or *Black Saltwort*. Root perennial, creeping; stems trailing, jointed, branched a little; leaves sessile, oval-oblong, or oval-lanceolate, succulent, opposite at bottom, but among the flowers alternate; flowers almost sessile, axillary, solitary, from about the middle of the stem, purple, greenish white, white, or striped.—It is found on the sea-coast, and on salt marshes at a distance from the sea, and even about Upsal, in Sweden, which is at a great distance from the ocean. It is a pretty little plant, enlivening large tracts of the dreary situations where it is found; the whole plant is succulent, and salt to the taste: cows eat it. It flowers in June, and continues the rest of the summer, and is seldom cultivated in gardens.

Glechoma; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, tubular, cylindric, streaked, very small, permanent; mouth five-cleft, acuminate, unequal. *Corolla*: one-petalled, ringent; tube slender, compressed; upper lip erect, obtuse, semibifid, lower spreading, larger, obtuse, trifid; middle segment larger, emarginate. *Stamina*: filamenta four, under the upper lip, of which two are shorter; each pair of antheræ converging in form of a cross. *Pistil*: germen four-cleft; style filiform, bending beneath the lip; stigma bifid, acute. *Pericarp*: none. *Calix*: cherishing the seeds in its bosom. *Seeds*: four, ovate. **ESSENTIAL CHARACTER.** *Calix*: five-cleft; each pair of antheræ converging in form of a cross.—The only species is,

1. *Glechoma Hederacea*; *Ground Ivy*, *Gill*, *Cat's-foot*, *Tun Hoof*, *Robin-run-in-the-hedge*, or *Alehoof*. Leaves kidney-shaped, crenate, or scalloped; root perennial, sending out trailing four-cornered shoots, producing roots at the joints, and spreading wide; the flowering-stalks spring from the joints, which are woolly, these are upright, but weak, square, hirsute, with pairs turning downward from four to six inches high; the leaves are beset underneath with hollow dots, in which are glands secreting an essential oil, and above with little eminences, but which do not secrete any odoriferous oil, so that this surface being rubbed gives out no peculiar scent, whereas the under surface affords a pleasant reviving smell: peduncles axillary, opposite, short, branched, supporting from three to five flowers; corolla blue, sometimes varying to white; the larger middle segment of the lower lip marked with purple dots of a deeper colour, and hairy at the base; stamina sometimes in the spring imperfect, with filamenta only half the usual length, terminated by a reddish blunt point, or sometimes by effete antheræ; when perfect, the antheræ after bursting form a cross, or the shape of the letter X; the leaves are often deformed with red hairy tumors, which are the galls of the cynips *glechomæ*. It gradually expels the plants which happen to grow near it, and thus impoverishes the pastures; the leaves were formerly thrown into the vat with ale, to clarify it, and to give it a flavour. This was called *gill-ale*, ground ivy being named *gill*, or *gill-creep-by-ground*, in some places. From this use of the plant, and the form of its leaves, it has also the names of *alehoof* and *tunhoof*, but has gradually fallen into

disuse since the introduction of hops. Cattle seem in general to avoid it, though Linnæus says that sheep eat it, horses are not fond of it; and it is refused by cows, goats, and swine. It is said to be injurious to those horses that eat much of it; although the expressed juice, mixed with a little wine, and applied morning and evening, destroys the white specks which frequently infest their eyes. This plant has a peculiarly strong smell, with a bitterish and somewhat aromatic taste; it was formerly in high repute for a pectoral, detergent, aperient, diuretic, corroborant, and was particularly recommended in pulmonary and nephritic complaints. In obstinate coughs it is still a favourite remedy with the country people, though seldom prescribed by medical practitioners, and wholly discarded from the *materia medica* of the London college. Mr. Ray cites a remarkable instance of its efficacy by drawing the juice of the plant up the nostrils; but Dr. Cullen will not allow it to be of any utility, except as an errhine: he thinks the use of it in ale to be frivolous, and declares, that in many cases where he had seen it employed, there was no evidence either of its diuretic or pectoral effects. The usual manner of taking it is in an infusion, or tea; the expressed juice is also used with honey in coughs; a conserve or syrup is also made with it. The distilled water is wholly useless. The conserve made of the young tops in the spring, or the juice made into a syrup, is excellent for colds, coughs, and shortness of breath; and the infusion, made strong, and drank as tea, is serviceable in all complaints of the breast and lungs. The expressed juice snuffed up the nose, is an excellent, and often an instantaneous remedy for the head-ache, and may be advantageously used in inflammations of the eyes, arising from external violence. Notwithstanding what Dr. Cullen advances against the use of this plant in ale, Meyrick asserts, that the leaves, when bruised, and thrown into the vat with the liquor, not only effectually clarify and give it an agreeable flavour, but also communicate an antiscorbutic virtue. It is so common under hedges, on banks, in woods, and sometimes in dry pastures, that it is never cultivated in gardens. It varies in size, as well as the degree of colour in the flower, according to its situation: the flowers appear in April, May, and June. A plant so universally esteemed by the multitude, was sure to acquire many names. To those already enumerated we have to add that of *hay-maids*: the Germans call it *gundelreben*, *gundermann*, *gründermann*, *gundelrab*, *gundrebe*, *gründrebe*, *gunderlunze*, *donnerrebe*, *erdpeheu*, *erdenkranzlein*, *meerwurzel*; the Dutch call it, *aardveil*, *hondsdrif*, *onderhave*; the Danes, *redbende*; the Swedes, *jordrefrot*; the Italians, *ellera terrestre*; and the Spaniards, *hiedra terrestre*.

Gleditschia; a genus of the class Polygamia, order Diœcia. —**GENERIC CHARACTER.** *Male*: a long, compact, cylindrical ament, *Calix*: perianth proper, three-leaved; leaflets patulous, like the calix; nectary turbinate, with the other parts of the fructification growing to the mouth. *Stamina*: filamenta six, filiform, longer than the corolla; antheræ incumbent, oblong, compressed, twin. *Hermaphrodite*: in the same ament with the males, usually terminating. *Calix*: perianth four-cleft, otherwise as in the male; nectary as in the male. *Stamina*: as in the males. *Pistil*, *Pericarp*, and *Seed*: as in the female. *Female*: a lax ament, on a distinct plant. *Calix*: perianth proper, as in the male, but five-leaved. *Corolla*: petals five, long, sharp, from upright spreading; nectaries two, short, like filamenta. *Pistil*: germ broad, flattened, longer than the corolla; style short, reflex; stigma reflex; stigma thick, the length of the style, along which it grows pubescent at top. *Pericarp*: legume very large, broad, extremely flattened, divided by several trans-

verse partitions, and filled with pulp. *Seeds*: solitary, roundish, hard, shining. **ESSENTIAL CHARACTER.** *Hermaphrodite*. *Calix*: four-cleft. *Corolla*: four-petalled. *Stamina*: six. *Pistil*: one. *Male*. *Calix*: three-leaved. *Corolla*: three-petalled. *Stamina*: six. *Female*. *Calix*: five-leaved. *Corolla*: five-petalled. *Pistil*: one. — The only known species is,

1. *Gleditschia Triacanthos*; *Three-horned Acacia*. Leaflets ovate-oblong; spines very frequent, in all the varieties axillary, and commonly triple. It rises with an erect trunk to the height of thirty or forty feet, and is armed with long spines, three or four inches long, which have two or three smaller ones coming out from the side, and are frequently produced in clusters at the knots of the stem; leaves bipinnate, composed of ten pairs of leaflets, of a lucid green, and sessile; the flowers come out from the side of the young branches, and being of an herbaceous colour, make no figure; legume nearly a foot and a half long, and two inches broad; seeds smooth, surrounded by a sweet pulp. The leaves seldom come out till June in this country, and the flowers not till the end of July; neither does the tree produce any flowers until it has grown to a large size. These trees are propagated by seeds, which must be procured from America; those of the first are annually sent to England in plenty, by the title of *locust*, or *honey-locust*, to distinguish them from the false acacia, which is frequently called locust-tree in America. The seeds may be sown upon a bed of light earth in the spring, burying them half an inch deep; and if the spring should prove dry, they must be frequently watered, otherwise the plants will not come up the first year, for sometimes the seeds remain two years in the earth before they appear; so that those who wish to save time, should sow the seeds as soon as they arrive, and plunge the pots into a moderate hot-bed, observing to water them frequently; by this method most of the plants will come up in the same season, but these should be gradually inured to bear the open air, for if they are continued in the hot-bed, they will draw up weak. The plants in pots will require frequent waterings during the summer season; but those in the full ground will require much less, except in very dry seasons. In autumn, those in the pots should be placed under a hot-bed frame, to protect them from frost, for these young plants generally keep growing late in the summer, and the upper part of their shoots being tender, the early frost of the autumn often kills the end of them, if they are not protected, and this frequently occasions great part of the shoots decaying in winter, for which reason, those plants in the full ground should be covered with mats in autumn, on the first appearance of frost, for a small frost in autumn will do more mischief to these young shoots which are full of sap, than severe frost when the shoots are hardened. In the following spring these plants may be transplanted into nursery beds, at a foot distance row from row, and six inches asunder in the rows; but this should not be performed till April, after the danger of harder frost is over, for as the plants do not put out their leaves till very late, there will be no hazard in removing them any time before May. If the season should prove dry, they must be watered; and if the surface of the beds be covered with moss or mulch, to prevent the earth from drying, it will be of great service to the plants, which may remain two years in these beds, during which time they must be constantly kept clean from weeds, and in the winter there should be some rotten tan or other mulch spread over the surface of the ground to keep out the frost. If the plants thrive well, they will be fit to transplant to the places where they are to remain after two years' growth, for they do not bear removing

when large; the best season for transplanting these trees is late in the spring; they thrive best in a deep light soil, for in strong shallow ground they become mossy, and never grow large; they should also have a sheltered situation, for when much exposed to winds, the branches are frequently broken, when fully clothed with the leaves, which do not appear till June. As this is an elegant tree, it should appear singly in the openings of plantations, wherever it can be well sheltered from cold winds.

2. *Gleditschia Monosperma*; *Swamp Locust Tree*. Branches somewhat thorny; little leaves ovate-oblong, sharp; pods containing only one seed: flowers in July, and is a native of Carolina and Florida. This plant is only considered, by Miller, a variety of the first species; but being fully satisfied, with Fred. Pursh, that it is entirely distinct from *Gleditschia Triacanthos*, we have copied his specific description.

Glinus; a genus of the class Dodecandria, order Pentagynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate, concave, coloured within, permanent. *Corolla*: none; nectaries often five, flat, resembling petals, narrow, shorter than the calix, unequally bifid or trifid. *Stamina*: filamenta about fifteen, (Gærtner says, fifteen to twenty,) subulate, flat, the length of the calix. *Antheræ* erect, upright, compressed, twin. *Pistil*: germen superior, five-cornered; styles five, short; stigmas simple. *Pericarp*: capsule ovate, five-celled, five-cornered, five-valved. *Seeds*: very many, roundish, in a single row under the valves, tubercled, affixed at the base to a small swelling membrane. *Observe*: The nectaries of Linneus are what Gærtner calls the petals. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: none; nectaries cloven bristles. *Capsules*: five-cornered, five-celled, five-valved, containing numerous seeds.—The species are,

1. *Glinus Lotoides*; *Hairy Glinus*. Stem hairy; leaves obovate; root annual; capsule ovate-pyramidal, thin, pustuled by the protuberating seeds; partitions inserted in the middle of the valves.—Native of the south of Europe, and the Levant.

2. *Glinus Dictamnoides*. Stem frutescent, prostrate; leaves orbicular, tomentose, flat; calicine leaflets lanceolate; branches alternate, both they and the stems tomentose at top, but with hairs less distinct than in the first species; peduncles at the joints aggregate, short.—Native of the East Indies.

3. *Glinus Setiflorus*. Stem shrubby; leaves obovate, plaited; calicine leaflets ovate. The whole plant is hoary, with very close hairs, longer than in the first species; flowers axillary, several; peduncles very short; spinules rigid, minute, from the base of the peduncles, permanent.—Native of Arabia.

Globba; a genus of the class Diandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth superior, one-leaved, cylindric, with a trifid mouth, permanent. *Corolla*: monopetalous, cylindric, with a trifid equal mouth. *Stamina*: filamenta two, filiform, middling in length. *Antheræ* fastened longitudinally to the filamenta. *Pistil*: germen inferior; style bristle-shaped, of a middling length; stigma sharp. *Pericarp*: capsule roundish, three-celled, three-valved. *Seeds*: very many. **ESSENTIAL CHARACTER.** *Calix*: superior, trifid. *Corolla*: equal, trifid. *Capsule*: three-celled. *Seeds*: very many.—The species are,

1. *Globba Marantina*. Spike terminating, erect; stem simple, herbaceous; flowers remote, each involved in an ovate bracte, longer than the flower.—Native of the East Indies.

2. *Globba Nutans*. Spike terminating, pendulous. Rumphius makes two varieties of this, the great and the small; the first has a very straight firm stem, from fourteen to eigh-

teen feet in height, two inches in diameter at bottom, naked for six feet from the root, and stout enough for walking canes; the upper, which is soft, is eaten in some places; leaves three feet long, and more than two hands broad, thin, smooth, with many parallel transverse veins, bending upwards near the edge, forming slight ridges on the upper, and furrows on the lower surface; fruit hollow, the size of a pigeon's egg, red; the leaves of the smaller sort are more wandering, narrower, and draw more to a point at the base; the primary stem is two or three feet in length, and leafless, producing abundance of oblong flowers in bunches, like the hyacinth.—Native of the East Indies.

3. *Globba Uviformis*. Spike lateral; stem from seven or eight to twelve or fourteen feet high, the thickness of a finger; leaves from fourteen to sixteen inches long, and from four to six fingers broad, smooth, and dark green above, pale green and lanuginose beneath; the fructification issues from the side of the stem, eighteen inches or two feet above the root, in a spathed bunch or spike a hand in length, containing many white flowers, which are succeeded by fruit resembling grapes, but larger, white, becoming black, or of the colour of smoke, and sometimes eaten.—Native of the East Indies.

4. *Globba Japonica*. Raceme terminating, drooping; leaves sword-shaped, entire; the stem is sheathed with leaves, simple, round, streaked, smooth, upright, two feet high or more; flowers many; rachis flexuose, a hand in length; peduncle scarcely a line long, nodding a little, one-flowered; style filiform; seeds surrounded by a white connecting membrane, angular, smooth, brown; capsule ovate.—Native of Japan, where the fruit ripens in December and January.

Globe Amaranth. See *Gomphrena*.

Globe Flower. See *Trollius*.

Globe Thistle. See *Echinops*.

Globularia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: common; perianth imbricate, with scales the length of the disk, and equal; proper one-leaved, tubular, five-cleft, sharp, permanent, four or five-toothed; the teeth bristle-shaped and acuminate, according to Gærtner. *Corolla*: universal, nearly equal; proper monopetalous, tubular at the base; border five-parted; upper lip very narrow, two-parted, shorter, lower of three larger equal segments. *Stamina*: filamenta four, simple, the length of the corollule. *Antheræ* distinct, incumbent. *Pistil*: germen ovate, superior; style simple, the length of the stamina; stigma obtuse. *Pericarp*: none; proper calix converging, inclosing the seed. *Seed*: solitary, ovate. *Receptacle*: common, oblong, separated by chaffs. **ESSENTIAL CHARACTER.** *Calix*: common, imbricate; proper tubular, inferior; corollets the upper lip two-parted, lower three parted. *Receptacle*: chaffy.—The species are,

1. *Globularia Longifolia*; *Long-leaved Globularia*. Stem shrubby, all the leaves linear-lanceolate, quite entire; heads axillary. This rises much higher than the next species, having a hard white wood, with a large pith, and a scabrous light brown or gray bark; the branches towards their ends very thick set with leaves, without any order, they are two inches long, and a third part of an inch broad in the middle; the nerves yellowish green; flowers small, blue, in round heads.—It flowers in July and August, and is a native of Madeira. This and the eighth species are somewhat too tender, and should be sheltered from the frost in winter under a frame, but in summer should be exposed with other hardy exotic plants, and will require to be frequently watered in dry weather. This may be propagated by seeds, or by parting their roots, as was directed for the fourth sort.

2. *Globularia Alypum*; *Three-tooth-leaved Globularia*. Stem shrubby; leaves lanceolate, three-toothed, and entire; heads terminating. This has a hard woody stem, about two feet high, with many woody branches, beset with leaves like those of the myrtle; the flowers are produced on the tops of the branches in a ball, and are of a blue colour. It flowers from August to November.—Native of the south of Europe, and of Barbary. From the violent purging quality of this shrub, it acquired the name of *frutex*, or *herba terribilis*, and in English, *herb terrible*; but in the abundance of purging medicines that we possess, this is seldom if ever used. This plant may be propagated by cuttings, which should be cut off in April, just before they begin to make new shoots; the cuttings should be planted into pots filled with light fresh earth, and then placed in a very moderate hot-bed, observing to water and shade them until they have taken root, when they may be taken out of the bed, and inured to bear the open air by degrees. In summer these plants may be exposed with other hardy exotic plants, and in winter they should be placed under a hot-bed frame, where they may enjoy the free air in mild weather, but should be screened from hard frost, which will destroy them if they are exposed thereto, but in mild winters they will live in the open air. It never produces good seeds in this country.

3. *Globularia Bisnagarica*. Stem shrubby; root-leaves wedge-shaped, retuse; stem-leaves lanceolate.—Native country unknown.

4. *Globularia Vulgaris*; *Common Globularia*, or *Blue Daisy*. Stem herbaceous; root-leaves three-toothed; stem-leaves lanceolate; root-leaves numerous, like those of the daisy, but thicker petioled, placed in a ring, ovate-obtuse, quite entire, emarginate; the nerve produced into a small awn or point; corollets of a fine blue; germen villose. It varies with a white flower, and with a leafless stalk. It usually flowers in May and June.—Native of many parts of Europe, as Sweden, the south of France, Germany, Switzerland, Austria, Carniola, Hungary, Savoy, Italy, and Spain. This, together with the fourth, fifth, sixth, and seventh species, may be propagated by parting the roots, after the manner of daisies. The best season for parting and transplanting of the plants is in September, that they may take new root before the severe weather comes on. They should be planted in a shady situation, and require a moist loamy soil, in which they will thrive much better than in a light ground and an open situation, but the plants should not be removed oftener than every other year, if required to flower strong.

5. *Globularia Spinoza*; *Prickly-leaved Globularia*. Root-leaves crenate, prickly; stem-leaves quite entire, mucronate; stem a hand in height, dark green, with oblong narrow leaves at the base, not notched, but ending in prickles; heads of flowers longer than in the preceding species.—It flowers in May, and is a native of Spain. See the fourth species.

6. *Globularia Cordifolia*; *Wedge-leaved Globularia*. Stem almost naked; leaves wedge-shaped, three-cusped, the middle cusp least; root large, woody, producing many tufts of leaves.—It flowers in June and July, and is a native of Switzerland, Austria, Carniola, Hungary, Piedmont, and Arragon. See the fourth species.

7. *Globularia Nudicaulis*; *Naked-stalked Globularia*. Stem naked; leaves quite entire, lanceolate; flowers usually trifid, but sometimes quadrifid.—It flowers in July, and is a native of Switzerland, Austria, Carniola, Savoy, and Piedmont.

8. *Globularia Orientalis*. Stem almost naked; heads alternate, sessile; leaves lanceolate-ovate, entire; root-leaves very many, obovate, naked, sharp, ending in the petiole.—Found in the Levant. See the first species.

Gloriosa; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, oblong-lanceolate, waved, very long, wholly reflex. *Stamina*: filamenta six, subulate, shorter than the corolla, from straight patulous; antheræ incumbent. *Pistil*: germen globular; style filiform, longer than the stamina, inclined; stigma triple, obtuse; pericarp capsule superior, oval, three lobed, three-celled, three-valved. *Seeds*: several, globular, berried in two rows. *Observe*. This genus is allied to erythronium. ESSENTIAL CHARACTER. *Corolla*: six-petalled, waved, reflex. *Style*: oblique.—The species are,

1. *Gloriosa Superba*; *Superb Lily*. Leaves tendril-bearing. This has a long fleshy root, of a whitish colour, and a nauseous bitter taste, from the middle of which rises a round weak stem, requiring support, and with that growing to the height of eight or ten feet; flowers at the upper part of the stem, from the side, on slender peduncles, hanging down, at first of an herbaceous colour, but changing to a beautiful flame colour. It flowers in June and July, but seldom perfects seeds in this country. The stalks decay in autumn; the roots remain inactive all the winter, and new stalks appear in March. The roots and every part of the plant are poisonous. Neither this nor the second species are often known to produce their seeds in this country; they are generally propagated by their roots; those of the first species creep and multiply pretty fast, but the second has not yet put out any offsets. The roots may be taken out of the ground when their stalks are decayed, and preserved in sand during winter; but they must be kept in the stove or a warm room, where they can receive no injury from the cold; and in the spring, they must be planted in pots filled with light earth, and plunged into the tan-bed in the stove: but others choose to let the roots continue in the ground all the winter; for as they are then in an inactive state, moisture at that time frequently rots the roots. Towards the latter end of March, or the beginning of April, their stalks will appear; and some tall sticks should be put down to support them, otherwise they will trail over the neighbouring plants, and the first species will fasten to the plant by the tendrils. The stalks of this species will rise ten or twelve feet high, if the roots be strong; and some of them will produce two or three flowers, which make a fine appearance during their continuance, but seldom last more than ten days or a fortnight. In summer, while growing, they will frequently require to be watered, but must only have small quantities, as they are always liable to rot. Those roots which are not taken out of the pots in winter, should be transplanted, and parted in the beginning of March, before they put out new fibres or stalks, for they must not be removed when they are in a growing state. The pots should not be over large, for unless the plants be rather confined, they will not put out strong stalks; the largest roots may be planted in two-penny pots, but the smaller will only require pots that are five or six inches wide at top.

2. *Gloriosa Simplex*. Leaves acuminate; stem climbing. The stalks have not yet grown more than two feet high, but have the appearance of climbing. The leaves have a strong disagreeable scent when handled, and the flower is said to be blue. For its propagation and culture, see the first species.

Glossoma; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, turbinate, four-toothed, superior, permanent. *Corolla*: petals four, lanceolate, acute, bowed back; nectary a rim round the base of the style. *Stamina*: filamenta four,

very short; antheræ oblong, almost united into a cylinder, prolonged at the tip into a membranaceous strap or scale, gaping on the inside. *Pistil*: germen inferior; style filiform, the length of the stamina; stigmas four, acute. *Pericarp*: drupe spear-shaped, one-celled, crowned with the calix. *Seed*: single, ovate, streaked. **ESSENTIAL CHARACTER.** *Calix*: turbinate, four-toothed, superior. *Corolla*: four-petalled. *Antheræ*: almost united, with a membranaceous scale at the end. *Stigmas*: four.—The only known species is,

1. *Glossoma Guianensis*. This is a middling-sized shrub, five or six feet high; the bark brown; the wood yellow, hard, and compact; branches jointed, and four-cornered; leaves opposite, cruciate, six inches long, and half an inch wide, entire, smooth, thick, elliptic, acuminate, on very short petioles; stipules short, acute, at the base of the petioles deciduous; peduncles axillary, bearing two, three, or four flowers, each on its proper pedicel, bracted at the base; corolla white.—It flowers in September, and is a native of Guiana, where *vitomita* is the vernacular name.

Glossopetalum; a genus of the class Pentandria, order Pentagynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, very small, five-toothed, permanent. *Corolla*: petals five, lanceolate, spreading, acute; at the tip of each a linear-lanceolate truncate strap, nearly the length of the petal, and lying in it. *Stamina*: filamenta five, very short; antheræ roundish. *Pistil*: germen roundish, surrounded by a gland bearing the petals and stamina; style none; stigmas five, acute. *Pericarp*: roundish, five-grooved, one-celled. *Seeds*: five, angular. **ESSENTIAL CHARACTER.** *Calix*: very small, five-toothed; petals five, with a strap at the tip of each.—The species are,

1. *Glossopetalum Glabrum*. Leaves smooth. This is a tree, the trunk of which rises to the height of sixty feet or more, and is from two to three feet in diameter. The bark is smooth and gray; the wood white, and of a loose texture. The petiole is short, and has two small, narrow, deciduous stipules at the base; peduncles solitary, axillary, two inches long, bearing many flowers in a spherical head; corolla yellow; berry black.—Native of Guiana, where it flowers in November: the natives make canoes of the trunk.

2. *Glossopetalum Hirsutum*. Leaves hairy. The trunk of this species is only from twenty to twenty-five feet in height. The bark is wrinkled, blackish, marked with white. The leaves are covered with short hairs on both sides. They are used against inflammations in the eyes; they are bitter, and so also is the bark.—Native of Guiana and Cayenne, where its vernacular name is *goupi*.

Gloxinia; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth superior, five-leaved; leaflets equal, lanceolate, serrulate at the tip; the three upper ones nerved, the two lower bent down with the nectary, permanent. *Corolla*: monopetalous, irregularly campanulate; tube scarcely any; border oblique, five-cleft; segments roundish, the four upper spreading and entire, the lowest straight, concave, toothed. *Stamina*: filamenta four, with the rudiment of a fifth, two scarcely shorter, inserted into the receptacle, fastened to the lower margin of the corolla, sickled, pubescent, converging laterally above; antheræ ovate, two-celled, peltate, united within the opening of the corolla. *Pistil*: germen inferior, turbinate, striated; style filiform, the length of the stamina; stigma capitate, the length of the antheræ. *Pericarp*: capsule one-celled, or half-celled; receptacles two, opposite, two-parted, fastened to the sides of the capsule by the partition. *Seeds*: very numerous, inserted into the receptacles. *Observe.* L'Her-

tier remarks, that it is distinct from *martynia*, by its inferior germen; from *gesneria*, by its bell-shaped corolla, with the upper segment bent back; and from *cyrilla* by its bell-shaped corolla, without the tricallos mouth. **ESSENTIAL CHARACTER.** *Calix*: superior, five-leaved. *Corolla*: bell-shaped, with the border oblique; filamenta with the rudimentum of a fifth inserted into the receptacle.—The only known species is,

1. *Gloxinia Maculata*; *Spotted Gloxinia*. Root perennial, thick, fleshy, divided into knots, which are scaly, somewhat like those of toothwort; stems several, about a foot high, thick, succulent, purplish, terminated by a short spike of blue flowers, or rather an erect raceme, leafy or bracted, in which the flowers are axillary, solitary, peduncled, bright blue, and sweet-scented; corolla hirsute on the outside, inserted into the receptacle, larger than the calix; the base is gibbous in front, very large, melliferous within, and dark purple.—Native of South America. This plant must be constantly preserved in the stove, and plunged into the bark bed. During the winter season, much water will rot the roots. In the middle of March, just before it begins to shoot, the roots may be parted, and transplanted into middling-sized pots, filled with light rich earth, and plunged into the bark-bed, which should then be renewed with fresh tan. When the plants come up, they must be frequently refreshed with water in small quantities; and as the season becomes warmer, a large share of fresh air should be admitted. They should not be placed where they are shaded or overhung by other plants; nor should they be shifted or transplanted when they are in leaf, for that will prevent their flowering. As this plant increases very fast by the roots, there is no necessity for using other methods to propagate it; otherwise, the shoots of the young stalks will take root, if they are planted in pots filled with light earth, and plunged into a hot-bed during any of the summer months.

Gluta; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, very thinly membranaceous, bell-shaped, obtuse, shorter than the germen, deciduous. *Corolla*: petals five, lanceolate, longer than the calix, spreading at top, but below, as far as the middle, glued to the column of the germen. *Stamina*: filamenta five, bristle-shaped, of a middling length, inserted into the tip of the column; antheræ versatile, roundish. *Pistil*: germen obovate, sitting on an oblong column; style filiform, of a middling length; stigma obtuse. *Observe.* If the petals be separated from the column of the germen, the situation of the stamina will be as in *passiflora*. **ESSENTIAL CHARACTER.** *Calix*: bell-shaped, deciduous; petals five, glued at bottom to the column of the germen; filamenta inserted into the tip of the column; germen sitting on an oblong column.—The only species yet discovered is,

1. *Gluta Benghas*. A tree, with branches leafy at the end; leaves alternate, sessile, broad lanceolate, about a foot in length, veined, naked, on the flowering branches only a hand long, more obtuse, and crowded; panicle terminating, peduncled, with flowers the size of those of cabbage; fructification singular; and if we were to suppose the petals to be separated from the column, the situation of the stamina would be as in *passiflora*.

Glycine; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, compressed; mouth two-lipped; upper lip emarginate, obtuse; lower longer, trifid, acute; the middle tooth more produced. *Corolla*: papilionaceous; banner obcordate; the sides bent down; the back gibbous; the tip emarginate, straight, repelled from the keel; wings oblong, towards the

tip ovate, small, bent downwards; keel linear, sickle-shaped, bent upwards; at the tip pressing the banner upwards, obtuse, towards the tip broader. *Stamina*: filamenta diadelphous, simple, and nine-cleft, only a little divided at the tip, rolled back; anthera simple. *Pistil*: germen oblong; style cylindric, rolled back in a spiral; stigma obtuse. *Pericarp*: legume oblong. *Seeds*: kidney-form. **ESSENTIAL CHARACTER.** *Calix*: two-lipped. *Corolla*: the keel turning back the banner at the tip.—The species are,

1. *Glycine Subterranea*. Leaves ternate, radical; stalks procumbent, flexuose; peduncles two-flowered; root annual; stalks several, a span in length, very rigid, close to the ground, or descending to it, round, hairy, unbranched; stipules two, lateral, permanent, very shortly peltate, ovate, quite entire, very small, hairy, flat; partial stipules to each lateral leaflet, solitary; to the middle one, two oblong, smooth, sessile, upright, concave; flowers upright; corolla pale yellow; banner obovate, streaked, upright; wings very blunt, as long as the banner, spread out; keel as long as the wings, blunt. As soon as this plant is out of flower, the peduncle perforates the earth, like the *trifolium subterraneum*, and *arachis hypogaea*, and the seeds ripen under ground.—It is a native of Brazil and Surinam, and is common on the coast of Africa. In Surinam, it is called the *gobbe gobbe*, and being planted in a sandy soil, with the addition of a little clay, bears abundance of fruit, which is a welcome repast to the inhabitants, who boil it before it becomes ripe, like green peas.

2. *Glycine Monoica*; *Pale-flowered Glycine*. Leaves ternate, almost naked; stalks hairy; racemes pendulous; fruit-bearing flowers apetalous; racemes many-flowered; flowers like those of *vicia cracca*, with the banner pale violet; the wings and keel white; they have the stamina and pistil, but the former being effete, they bear no fruit.—It flowers here in September, and is a native of North America.

3. *Glycine Debilis*; *Hairy Glycine*. Leaves ternate; leaflets oval, hairy underneath; legumes subsolitary, linear, many-seeded; style permanent, upright; root biennial.—It flowers in July, and is a native of the East Indies.

4. *Glycine Caribbæa*; *Trailing Glycine*. Leaves ternate, subvillose; leaflets rhomb-shaped; racemes patulous; legumes hirsute; stalk shrubby, twining; racemes axillary, lateral, slender, elongated, many-flowered; corolla yellow; the banner variegated underneath with purple lines; legume an inch long. It flowers in September and October.—Native of the West Indies.

5. *Glycine Triloba*; *Three-lobed Glycine*. Leaves ternate; leaflets lobed; stalk prostrate; peduncles two-flowered. The whole plant is prostrate, and does not climb. The root is annual. The flowers are yellow, smaller, and generally two together.—Native of the East Indies.

6. *Glycine Villosa*; *Villose Glycine*. Leaves ternate, three-lobed, villose; racemes axillary; stem filiform, angular, twining, flexuose, tomentose, as is also the whole plant; raceme peduncled, with two, four, or five flowers.—Native of Japan.

7. *Glycine Javanica*; *Java Glycine*. Leaves ternate; stalk villose; petioles rough-haired; bractes lanceolate, minute; stem twining, with yellow reflex hairs scattered over it; pedicels yellow, with close hairs; stipules to the petioles oval, long, to the peduncles lanceolate; peduncles the length of the leaves, terminated by an ovate-oblong close spike, of nodding violet-coloured flowers, with very minute bractes between them.—Native of the East Indies, and near Nagasaki in Japan, where it is called *fajo mame*, and flowers in September and October.

8. *Glycine Comosa*. Leaves ternate, hirsute; racemes lateral. This rises from two to three feet high, with slender herbaceous stalks; flowers axillary, lateral; the naked part of the peduncle is about two inches long; the spike is about the same length, and recurved; corolla small, of a fine blue colour.—Native of moist shady places in Virginia. This and the tenth species are hardy enough to endure the open air in England. They may be propagated by seeds, or by parting of the roots; the former is the best method, where good seeds can be obtained. They may be sown on a bed of light earth in the spring; and, if the season should prove dry, they must be frequently refreshed with water, otherwise they will remain long in the ground, without vegetating. When the plants come up, they must be kept clean from the weed, in the summer; and in the autumn, when the stalks are decayed, if some rotten tanner's bark be spread over the surface of the ground, it will protect the roots from being injured by the frost. In the spring, the roots should be transplanted to the places where they are designed to remain, which must be in a warm sheltered situation, but not too much exposed to the sun, and in a light soil, where they will thrive, and produce flowers annually. If they be propagated by parting of the roots, it should be done in the spring, before the roots begin to shoot; but they should not be parted oftener than every third year; for when they are often removed, they will not flower so strong.

9. *Glycine Phaseoloides*. Leaves ternate, villose underneath; racemes terminating; stem twining to a considerable height, and bearing many flowers towards the top. The legumes have two seeds, and are contracted in the middle.—Native of Jamaica and St. Domingo.

10. *Glycine Tomentosa*; *Downy Glycine*. Leaves ternate, tomentose; racemes very short, axillary; legumes two-seeded; root perennial; stalks twining, from a foot and a half to four feet in height, three-cornered, hairy. From the bosom of the leaves, three or four small flowers come out, on very short peduncles, of a pale yellow colour; the banner broadish, the wings narrow, and the keel compressed. The plant called *dolichos pubescens* by Linneus, is probably only a variety of this species.—Native of Virginia, where it is called *mountain pea*. It flowers from June to September, and ripens the early flowers in autumn. In addition to what is said under the eighth species, we have here to add, that as this is the tenderest of the two, the seeds may, for greater security, be sown in a hot-bed, and some of the plants kept in the green-house, or against a south wall, to be protected occasionally in severe weather, by putting dung to the roots.

11. *Glycine Reticulata*; *Netted-leaved Glycine*. Leaves ternate, oblong, lanceolate, pubescent; the veins like network underneath; racemes axillary, subsessile; legumes oblong, compressed; stem twining, angular, softly villose, subcanescent; pedicels solitary, distant; bractes ovate, attenuated, deciduous; seeds two.—Native of Jamaica.

12. *Glycine Bituminosa*; *Clammy Glycine*. Leaves ternate; flowers racemed; legumes tumid, villose; stem twining, obtuse, angled, pubescent; stipules ovate, acuminate, nerved; corollas yellow, streaked on the outside, and at the tip of the keel violet-coloured; seeds four, small, globular, a little flattened, black.—It flowers from April to September, and is a native of the Cape of Good Hope. This, together with the twenty-first, twenty-third, twenty-fourth, and twenty-fifth species, may all be raised from seed in the green-house or cape-stove.

13. *Glycine Nummularia*. Leaves ternate, very obtuse; racemes with flowers in pairs; legumes sessile, suborbiculate, compressed; stem herbaceous, twining, angular, pubescent;

petioles the length of the leaves; stipules ovate, deciduous; peduncles axillary, solitary, filiform, longer than the leaves, standing out undivided; flowers in three pairs, very remote, sessile, reflex, small.—Native of the East Indies.

14. *Glycine Labialis*; *Labiate Glycine*. Twining: leaves ternate, obovate, somewhat hoary; flowers axillary, heaped; corolla somewhat two-lipped; stalk twining, the thickness of a thread; stipules none; peduncles very short; calix tubular, five-toothed; the teeth nearly equal; style short.—Native of the East Indies.

15. *Glycine Striata*. Twining: leaves ternate, oblong, very softly hoary; racemes axillary, the length of the leaves; legumes extremely hirsute; stems woody, round, hirsute; petioles hirsute, round, not grooved or angular. All the stipules linear, and acuminate; calix hairy, one-third shorter than the petals; the tube bell-shaped and very short; the limb four-cleft; the clefts lanceolate and acuminate; the lowest a little longer, the uppermost broader, not emarginate; banner of the corolla striated, purple, green at the base, without any calluses; wings erect, narrower and shorter than the keel, purple; keel almost without colour, the length of the banner, cloven at the back almost to the top, emarginate in front at the tip; germen hairy, linear, compressed; style of the same length and in the same situation with the stamina, ending at top in a blunt dusky stigma, not bearded; seeds several, shining brown, variegated.—Native of South America.

16. *Glycine Rosea*. Twining: leaves ternate; leaflets cordate, ovate, acute, quite entire; peduncles three-flowered; legumes compressed, keeled, one-seeded.—Native of the Society Islands in the South Seas.

17. *Glycine Lucida*; *Shining Glycine*. Twining: leaves ternate; leaflets ovate, acuminate, quite entire; racemes terminating, glandular; pedicels in threes; legumes inflated, containing two seeds.—Native of the Society Islands in the South Seas.

18. *Glycine Suaveolens*; *Sweet Smelling Glycine*. Shrubby, upright, hoary: leaves ternate, ovate, acute; flowers axillary, solitary; legumes containing two seeds. The whole of this shrub is hoary, clammy, and sweet; peduncles upright, filiform, jointed, and bracted in the middle, one-flowered; bractes in pairs, subulate, caducous; seeds black, smooth, with a callous whitish heart.—Found by Kœnig, among rocks, near Madras in the East Indies.

19. *Glycine Apios*; *Tuberous-rooted Glycine*. Leaves unequally pinnate, ovate-lanceolate, with seven leaflets. This has a tuberous root, from which, in the spring, come out slender twining stalks, which rise the height of eight or ten feet. The flowers come out in short spikes from the sides of the stalks; they have little scent, appear in August, but do not produce seeds in England. Parkinson calls this plant *Virginia earth-nuts*. It is propagated by parting the roots, and each of the tubers will grow: the best time for this, is at the end of March, or the beginning of April, before they put out shoots. The roots should be planted in a warm situation, and, in hard frost, covered with tan or mulch to protect them, otherwise they will not live abroad in this country; where they have been planted against a south wall, they have thriven and flowered extremely well, which they seldom do in any other situation; and those which are planted in pots rarely flower, nor do their stalks rise nearly so high as those which are planted in the full ground.

20. *Glycine Frutescens*; *Shrubby Glycine*, or *Carolina Kidney-bean Tree*. Leaves unequally pinnate; stalk perennial, woody, twisting themselves together, and twining

round any trees that grow near, and will rise to the height of fifteen feet or more. The flowers are produced in clusters from the axils, and are of a purple colour. They appear from June to September. It is increased by laying down the young branches in October, which will be well rooted in twelve months from that time, especially if they are duly watered in dry weather, and may then be transplanted, either into a nursery for a year to acquire strength, or to the place where they are to remain for good, which should be in a warm light soil, and a sheltered situation, where they will endure the cold of our ordinary winters very well; and, if their roots be covered with straw, fern, peas-haulm, or any other light covering, there will be no danger of their being destroyed by the frost.—Native of the Cape of Good Hope.

21. *Glycine Monophylla*; *Simple-leaved Glycine*. Leaves simple, cordate; stalk pubescent, three-cornered; stipules in pairs; peduncles axillary, solitary, one-flowered, capillary, longer than the petioles; germen villose.—Native of the Cape of Good Hope. It flowers in August. See the twelfth species.

22. *Glycine Picta*. Leaves ternate, lanceolate, villose; racemes axillary, peduncled; stem erect, shrubby; branches angular, striated, subtomentose, with purplish hairs; petiole very short; stipule opposite to the leaf, sub-bifid; the segments awl-shaped; pedicels short; flowers spreading, approximating; calix hoary, two-lipped.—Found in Guiana, and in the island of Trinidad. It requires the protection of the bark-stove.

23. *Glycine Bimaculata*. Stem twining, smooth, and even; leaves simple, cordate, oblong; racemes many-flowered. This plant rises up with a twining shrubby stalk, to the height of six or eight feet or more; multiplying greatly by age, it becomes loaded with a profusion of purple flowers, growing in racemes; the richness of the corolla is enlivened by two green-spots at the base of the banner. In England, the flowers generally fade, without producing any seed-vesicles; though perfect seeds have been ripened, from which a plant was produced, that bore flowers in the garden of John Ord, Esq. at Walham Green. It begins to flower in February; and continues during the summer: it is one of the first Botany Bay plants that flowered in this country, and is one of the most ornamental. Mr. Curtis thinks, that both this and the next species may probably succeed in the open air, in warm sheltered situations, especially if a little protected in severe weather. See the twelfth species.

24. *Glycine Rubicunda*. Stem perennial, twining; leaves ternate; leaflets suboval, quite entire; peduncles subtriflorous. Almost the whole plant is covered with hairs, pressed close; corolla scarlet, mixed with dull purple; banner bent back, so as to lie on the calix, and cover it, scarlet on the ends and on the sides, purple in the middle, except towards the base, where it is whitish; stamina very manifestly diadelphous. It flowers from April to June, and is a Native of New South Wales. See the twelfth and twenty-third species.

25. *Glycine Coccinea*. Leaves ternate; leaflets roundish, waved, shrubby, climbing, growing many feet high when supported, and producing a great number of flowers on its pendent branches; flowers generally in pairs, of a glowing scarlet colour, rather inclined to purple at the base of the keel; the bottom of the banner is decorated with a large yellow spot, verging to green.—It flowers from April to June, and is lately introduced from New South Wales. See the twelfth species.

Glycyrrhiza; a genus of the class Diadelphia, order De-

candria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, two-lipped, permanent; upper lip three-parted; the lateral segments linear; the middle one broader, bifid; lower entirely simple, linear. *Corolla*: papilionaceous; banner ovate-lanceolate, straight, longer; wings oblong, very like the keel, but a little larger; keel two-petalled, acute, with a claw the length of the calix. *Stamina*: filaments diadelphous, (simple and nine-cleft,) straight; antherae simple, roundish. *Pistil*: germen shorter than the calix; style subulate, the length of the stamina; stigma obtuse, ascending. *Pericarp*: legume ovate or oblong, compressed, acute, one-celled. *Seeds*: very few, kidney-form. **ESSENTIAL CHARACTER.** *Calix*: two-lipped; upper lip three-parted; lower undivided; legume ovate, compressed.—The species are,

1. *Glycyrrhiza Echinata*; *Prickly-headed Liquorice*. Legumes prickly; leaves stipuled, with the terminating leaflets sessile. The flowers appear in a roundish head; they are produced in shorter spikes than those of the second species; the pods are very short, and broad at their base, end in acute points, and are armed with sharp prickles. It flowers from April to June, and in warm seasons will perfect seeds in England.—Native of Apulia, the north of China, and of Tartary.

2. *Glycyrrhiza Glabra*; *Common Liquorice*. Legumes smooth; no stipules; the terminating leaflet petioled. The roots run very deeply into the ground, and also creep to a considerable distance, especially where they stand long unremoved. From these arise strong herbaceous stalks, four or five feet high; leaves composed of four or five pairs of ovate leaflets, terminated by an odd one; these and the stalks are clammy, and of a dark green; flowers in axillary spikes, standing erect, and of a pale blue colour; pods short, containing two or three seeds.—Native of the south of Europe, France, Spain, Italy, also of China, where it is cultivated, as well as in Germany and England, particularly near Pontefract in Yorkshire, Worksop in Nottinghamshire, Godalmin in Surry, and, of late years, in the gardens near London. It appears from Turner's Herbal, that it was cultivated in England in 1562; and Stow expressly says, "the planting and growing of licorish began about the first year of Queen Elisabeth," (1558.) Gerarde, in 1597, says, that he has plenty in his garden; and the poor people of the north parts of England manured it with great diligence, whereby they obtained great plenty. Ray asserts the English liquorice to be superior to the foreign. The quantity now imported from Spain, is said to be annually not less than 5000 quintals, or nearly 250 tons; a considerable part of which, is supposed to be used by the porter brewers of London. Liquorice-root contains a great quantity of saccharine matter, with some portion of mucilage. Lightly boiled in a little water, it gives out nearly all its sweetness: the decoction, pressed through a strainer, and inspissated with a gentle heat till it will no longer stick to the fingers, affords a better extract than that brought from abroad, under the name of *Spanish juice*, and will often amount in quantity to nearly half the weight of the root. Large quantities of extract of liquorice have been annually imported from Spain, but the shops seldom afford any that is perfectly genuine. The makers, both foreign and domestic, being either very slovenly in the preparation, or else they designedly mix it with sand, and other impurities. When carefully extracted, it is exceedingly sweet, more agreeably tasted than the root itself, and of a pleasant smell. It dissolves in boiling water, without leaving any sediment. Rectified spirit takes up the sweet matter of the liquorice, equally with water; and as it dissolves much less of the insipid mucilage,

the spirituous tincture and extract are sweeter than the watery. Before the roots are boiled, it is best to cut them into small pieces, that they may more readily give out their virtues; for if the boiling be too long continued, the rich sweet taste for which the extract is so justly esteemed, will be greatly injured. For the same reason, the quantity of water ought not to be longer than what is absolutely necessary to extract the virtues of the root. A quart, or at most three pints, will be found a sufficient quantity for a pound of liquorice. It would be of considerable advantage to the preparation, and probably less expensive to the preparers, to use the juice of the roots, which might be obtained by pressing them between iron rollers, in the manner practised in the West Indies for obtaining the juice of the sugar-cane, instead of the above process of decoction. Both the extract and the fresh root, in substance, are excellent for coughs, hoarseness, shortness of breath, and other disorders occasioned by an acrimonious state of the humours. They promote expectoration, thicken the juices, increase the urinary discharge, and are serviceable in the gravel and similar disorders. It was prescribed by the first practitioners in physic, in dropsies, to prevent thirst, for which it is indeed an excellent thing, though probably the only one of the sweet class that does so; sugar, and other substances of a like nature, generally increasing, rather than alleviating that sensation. The infusion is also a commodious vehicle for other medicines. Most plants thrive best in a rich soil, but liquorice will not grow in any other; and to have it in any degree of perfection, the soil must not only be rich, but deep, as the thriving of it depends entirely on those two circumstances. We expect to see the roots of this plant a yard or more in length; and it must have a free passage, otherwise they will not be straight, which regularity of form is not only more pleasing to the eye, but a real advantage, for the crooked ones are never so tender or full of juice as the other, nor do they attain their due degree of growth in so short a time. The proper ground then for producing liquorice in perfection, should have a coat of mellow black mould, at least three feet deep, without any great mixture of other matter in the way. This is the best natural soil for this valuable plant, and where it can be procured should always be preferred. But there are other soils, which, though not quite so well adapted by nature for the culture of liquorice, may be so prepared by art and industry, as very well to answer the purpose. The best of these are, first, a rich loam, without much clay in its composition; and, secondly, a deep, warm, sandy soil that is not barren, but, together with its lightness and dryness, has some richness. In all these soils, the depth must be at least a yard, before there is any hard bottom; and that must be examined, for if it should turn out a clay, the liquorice will never thrive, because of the coldness and moisture with which such an under stratum is always attended; the wet lodging upon it, and starving the whole soil. To ensure success in the planting of liquorice, the soil should possess the four following properties: depth, that it may penetrate and attain its full growth; lightness, that it may make its way easily; warmth, to promote its growth; and richness, to afford it nourishment. Liquorice, though raised in the field, requires a kind of garden culture, and the spade is a much more proper instrument to prepare the land with for its reception than the plough, for it requires to be broke, and made fine to a depth which the latter can never reach. There is one comfort, however, arises to the husbandman, which is, that if the land requires an expensive tillage, only a small quantity is required, as a few acres will yield an amazing produce of this root; and the price it will bear is so

much greater than that of most other things he can raise on it, that there is no room left for him to repine at the charges. Having therefore made choice of a proper piece of land for the purpose, let it be thoroughly dunged with good rotten dung, and after being ploughed up in the latter end of the summer, and lying all the winter to mellow, in the spring let it be dug in the following manner. In the middle of February, let the labourers be sent in, and properly looked over, to see that they do not perform their work slightly. They must dig every part of the earth thoroughly to the depth of three feet, and take care to break every lump they meet with, though but small, in order that the ground may lie smooth, with a level surface, and be nearly as fine as sand all the depth. The expense of doing this is very considerable, but it is absolutely necessary; the profit will be answerable; and the husbandman may rest assured, that by every shilling he would save in not having this work well performed, he would lose ten at least in the crop. When the whole piece of ground intended for the plantation is thus prepared, the sets are to be put in, and the same care and attention are requisite here, as in the other parts of the business, for the least omission or neglect is sure to be attended with loss. The first thing to be regarded in this respect, is the choice of the plants or sets; and the second is, placing them properly in the ground. Choice should be made of such only as are in good condition, and have, as the planters call it, a good eye or bud. They are either raised from seeds, or procured from the heads of the old roots, most commonly the latter, and should be about a foot in length, sound, fresh, and clear on the surface. About the beginning of March, when the sets are chosen, and the ground is perfectly prepared, is the season for planting, which should be performed in the following manner. Let there be got in readiness a gardener's line, of such a length as to extend from one side of the ground to the other, if it be but small; but if larger, it may be removed from place to place occasionally. A couple of sticks sharpened at the end, and a ball of cord, is all that is necessary for this purpose. Besides the line, the planter must be furnished with a setting-stick, which may be of any convenient length; but the best way is to have it of a certain dimension, that it may serve for a measure; and for this purpose, it should be just a foot and a half long, with a handle or crutch at the top like a spade, and a point made of a square piece of iron in form of a very large spike, and hollowed at the upper end to receive the wood. All things being in readiness, let the line be drawn at about the distance of a foot from the outside of the prepared ground. The planter then, taking his sets in his apron, or a basket, and the setting-stick in his hand, may begin to plant, placing the first set at about half the stick's length from the end of the line. When he has done this, let him measure from it along the line the length of his setting-stick, and at that distance plant another, and so on for the whole length. The manner of putting in the sets is this: let the end of the setting-stick, which is pointed with iron, be thrust into the ground till the handle almost touches the surface, and then being gently drawn out again, there will remain a hole about sixteen inches deep, into which is to be put a set of the liquorice, carefully and evenly thrusting it down till the head of it, where the bud or eye is, be one inch or a little more below the surface; the other end will then about reach the bottom of the hole, and a little mould being drawn over the top, the set will be completely well planted. The remaining part of the row is to be planted exactly in the same manner, and when that is completed, a second is to be begun at the distance of two feet and a half from it. But in planting this, it will be best not to place the

plants exactly opposite to those in the last row, but in the middle between them. The second row being put in, the line is to be drawn for a third, and the plants in this should be set opposite to those in the first row, which being done, every fourth plant of the first and third row will have one plant of the second row in their centre. This method is to be followed throughout the whole field, and is called the quincunx manner of planting; the effect of which is, that look which ever way you will at the plantation, when the stems are risen, they will appear in regular rows the whole extent of the ground. The whole being planted, the earth is to be finely raked, and the surface made perfectly level. Thus it is to be left for the present; and the advantages of so regular a piece of husbandry will sufficiently recompense the planter's trouble. The heads of the young plants will quickly appear, and weeds of the annual kinds will spring up in abundance along with them; these may be easily and expeditiously destroyed by going over them with the hand-hoe. This hoeing must be occasionally repeated during the summer; the expense attending it will be but small, and all the care requisite in performing it is, to avoid cutting or wounding the young plantation. The ground being thus kept clear during the summer, it will be well worth while to turn the whole over, one spit deep between the rows, as soon as the leaves begin to decay: and a month or two after, let a small quantity of very rotten dung be scattered all over the surface; this will cover the crowns of the young plants, and defend them from the severity of the winter's frost, and when those are past, the rains will in a manner dissolve the very substance of the dung, and convey its riches into the heart of this fine loose earth, for the better nourishment of the plants. In the spring, what remains will be dug in by turning the spaces between the rows over again, where, by mixing and fermenting with the mould, it will break and divide the soil, as well as enrich it farther. All that remains to be done the second summer, is to keep the plants free from weeds; and at the end of the third, they will be ready to take up for use.

3. *Glycyrrhiza Hirsuta*; *Hairy Liquorice*. Legumes hirsute; the terminating leaflet petioled. This strongly resembles the two preceding species, but the pods are hairy and longer.—Native of the Levant.

4. *Glycyrrhiza Asperima*; *Rough Liquorice*. Leaflets elliptic, cusped; stalk hispid, scabrous; legumes smooth; roots slender and very long, extremely sweet, especially in the spring. The flower pale violet colour.—Found between the Wolga and the Jaick.

Gmelina; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, very small, subglobular, four-toothed, permanent. *Corolla*: one-petalled, bell-shaped, patulous; the border four-cleft; the upper segments wider and vaulted; the lower and lateral segments obtuse, smaller, spreading, rounded. *Stamina*: filamenta four, two of which are thicker, and two bowed in and ascending. *Antheræ*, two thicker, parted, two smaller, simple. *Pistil*: germen roundish; style the length of the smaller stamina; stigma simple. *Pericarp*: drupe ovate, one-celled. *Seed*: nut ovate, smooth and even, two-celled; Gærtner says three-celled, with the lowest cell barren. ESSENTIAL CHARACTER. *Calix*: slightly four-toothed. *Corolla*: four-cleft, bell-shaped; *antheræ* two-parted, two simple; drupe with a two or three-celled nut.—The only species is,

1. *Gmelina Asiatica*. A tree with round, stiff, upright branches; leaves opposite, petioled, ovate, tomentose underneath, having frequently a shorter sharp lobe on each side; spines axillary, opposite, horizontal, pubescent at the tip,

the length of the petioles; flowers from the end of the tender twigs, on peduncles; the fruit a berried drupe, the size of jujubes, black and smooth; the shell bony, thick at top, with two small lateral lobes, remarkably acuminate at bottom.

Gnaphalium; a genus of the class Syngenesia, order Polygamia Superflua.—**GENERIC CHARACTER.** *Calix*: common, rounded, imbricate, with the marginal scales rounded, scariose, coloured. *Corolla*: compound; corollets hermaphrodite, tubular, with apetalous females sometimes intermixed; hermaphrodites funnel-form, with a five-cleft reflex border. *Stamina*: in the hermaphrodites; filamenta five, capillary, very short. *Antheræ* cylindric, tubulous. *Pistil*: germen ovate; style filiform, the length of the stamina; stigma bifid; in the females reflex. *Pericarp*: none. *Calix*: permanent, shining. *Seeds*: solitary, oblong, small, crowned with a capillary or feathered down. *Receptacle*: naked. *Observe*: The second species has a woolly receptacle. Some species have diœcous flowers, which is singular in this class. **ESSENTIAL CHARACTER.** *Calix*: imbricate, with the marginal scales rounded, scariose, coloured. *Down*: feathered, or simple. *Receptacle*: naked.—The species are,

* *Shrubby, with white flowers.*

1. *Gnaphalium Eximium*. Leaves sessile, ovate, crowded, upright, tomentose; corymb sessile; stem the thickness of a finger, and tomentose; flowers globular, with the calices as large as the outer joint of a finger, consisting of imbricate, roundish, scariose, concave, obtuse, smooth, purplish scales.—Native of the Cape of Good Hope. This may be increased by slipping off the heads, or by cuttings, during any of the summer months; they should be planted in a bed of light earth, or in pots in a gentle hot-bed, and covered with hand-glasses, or shaded with mats, observing to refresh them frequently with water in small quantities; these cuttings will put out roots in six or eight weeks, and must then be planted in pots filled with light earth, and placed in a shady situation till they have taken new root, when they may be removed to an open one, and placed among other hardy exotics, till the middle or end of October, at which time they should be placed under a common frame, where they may be protected from frost, but in mild weather they should be exposed to the open air.

2. *Gnaphalium Arboreum*; *Tree Everlasting*. Leaves sessile, linear, smooth on the upper surface, rolled back along the edge; flowers in a kind of head, on elongate peduncles. This is a shrub the height of a man, determinately branched; corymb very much crowded. It flowers during most part of the year.—Native of the Cape of Good Hope. It is propagated and cultivated in the same manner as directed for the first species.

3. *Gnaphalium Grandiflorum*; *Great-flowered Everlasting*. Leaves stem-clasping, ovate, three-nerved, lanuginous on both sides; branches round, simple, tomentose; flowers large, roundish, snow-white, in roundish, heaped, solitary cymes, on long tomentose scaly peduncles.—Native of the Cape of Good Hope. Propagated in the same way as the first species.

4. *Gnaphalium Fruticans*. Leaves ovate, stem-clasping; stem rigid; cyme sessile; stem the thickness of a finger, determinately branched, villose; flowers terminating, and heaped into a sessile head; calix yellow on the outside, but white within.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

5. *Gnaphalium Crispum*. Leaves tomentose underneath, scabrous above; root-leaves petioled, oblong; stem-leaves embracing, waved; peduncle elongated, tomentose, termi-

nated by a compound many-flowered cyme; flowers small; outer calices red, inner yellow.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

6. *Gnaphalium Appendiculatum*. Leaves sessile, imbricate, lanceolate, woolly, appendicled at the tip, with a scariose membrane; stem clothed with leaves up to the cyme. It is remarkable for a little, lanceolate, scariose membrane, terminating the leaf.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

7. *Gnaphalium Coronatum*. Leaves sessile, lanceolate; corymbs compound, sessile; peduncles leafless; calices crowned; stems woody, with villose branches.—Native of the Cape of Good Hope. Propagation and culture like that of the first species.

8. *Gnaphalium Discolorum*. Leaves sessile, lanceolate; calices white, lower scales flesh-coloured; stems under-shrubby; common peduncles elongated.—Native of the Cape of Good Hope. Propagated in the same manner as the first species.

9. *Gnaphalium Muricatum*. Leaves subulate, mucronate; umbel compound; calices cylindric, containing about three flowers; stem erect, round, pubescent; branches patulous, simple, alternate, or somewhat heaped, lightly tomentose. This varies with leaves, sharp or prickly, like those of juniper.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

10. *Gnaphalium Erioides*; *Heath-leaved Everlasting*. Leaves sessile, linear; outer calices rude, inner flesh-coloured; the branches are wand-like, rigid, unequal.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

11. *Gnaphalium Teretifolium*. Leaves crowded, almost columnar; corymbs branched; calices ferruginous on the outside; stem ash-coloured, round, submentose; branches leafy, white, tomentose; branchlets determinate, umbelled, erect, each loaded in the middle with other short aggregate branchlets.—Native of the Cape of Good Hope. It is cultivated in the same manner as the first species.

** *Shrubby, with yellow flowers.*

12. *Gnaphalium Mucronatum*. Leaves subulate, mucronate; calicic scales roundish; branches a span long, erect, simple, round, slightly tomentose, ash-coloured; flowers six, large, in panicles, terminating, contracted, on one-flowered tomentose peduncles.—Native of the Cape of Good Hope. Propagated in the same way as the first species.

13. *Gnaphalium Stoechas*; *Common Shrubby Everlasting*. Leaves linear; corymb compound; branches wand-like; stem about three feet high, with long slender irregular branches, the lower ones having blunt leaves two inches and a half long, and an eighth of an inch broad at the end; those on the flower-stalks are very narrow, and end in acute points. The whole plant is very woolly; flowers terminating in a compound corymb; calices at first silvery, but turning to a yellow sulphur. If gathered before the flowers are much opened, the heads will continue in beauty many years, if kept from air and dust. The flowers have been formerly recommended as attenuants, discutients, and diaphoretics, but are not used in common practice.—Native of Germany, France, Spain, and Italy. This, together with the thirteenth, fourteenth, twenty-fifth, and thirty-sixth species, is so hardy as in very mild winters to live abroad in warm borders near walls, with little shelter.

14. *Gnaphalium Ignescens*; *Red-flowered Everlasting*. Leaves sub lanceolate, tomentose, sessile; corymbs alternate, conglobate; flowers globular. See the above.

15. *Gnaphalium Dentatum*. Leaves wedge-shaped, toothed, sessile; corymb simple. The whole plant is hoary; branches scarcely a span long, and round; flowers at the ends of the branchlets few, small, shining, in oblong heads. See the first species.

16. *Gnaphalium Serratum*. Leaves stem-clasping, lanceolate-serrate, naked on the upper surface. This is an elegant plant, suffruticose, soft and silky, yellow, much branched, with procumbent, simple, pubescent runners; flowers terminating, very many, in a close compact head, each on short pedicels. See the first species.

17. *Gnaphalium Patulum*; *Spreading Everlasting*. Leaves stem-clasping, spatulate; corymbs aggregate; branches spreading; branches filiform, a foot or more in length, round, white, tomentose, patulous, somewhat branched; cymes terminating, loose, on long peduncles, tomentose, leafless; branches simple, and branchletted; flowers large, peduncled. It flowers from August to January. See the first species.

18. *Gnaphalium Petiolatum*. Leaves ovate, quite entire, petioled; flowers crowded, terminating. Propagated in the same manner as the first species.—Native of the Cape of Good Hope.

19. *Gnaphalium Crassifolium*; *Thick-leaved Everlasting*. Leaves broad-lanceolate, subpetioled, leathery, tomentose; corymb compound; stalk proliferous; stem a foot high, proliferous, branched, perennial, except the proliferous branch; flowers numerous. It flowers from July to September.—Native of Majorca and Minorca. It is propagated in the same manner as the first species.

20. *Gnaphalium Maritimum*; *Sea Everlasting*. Very much branched; leaves lanceolate, sessile, sharpish; inmost calicine scales gold-coloured. This shrub is four feet high, with pubescent branches; corymbs terminating, close, roundish, on very short peduncles; flowers gold-coloured.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

21. *Gnaphalium Repens*. Leaves linear; stem creeping, straight; branches upright, very simple; heads of flowers terminating, and glomerate.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

22. *Gnaphalium Umbellatum*. Leaves in bunches, subulate, twisted; umbels simple, terminating, sessile. The herb of this plant bears a strong resemblance to the ninth species, but it differs in having a regular umbel, larger flowers, and the scales of the calix are of a beautiful red.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

23. *Gnaphalium Hispidum*. Leaves linear, semicylindric, grooved, hispid, patulous; heads terminating, simple. This species is easily known by the stiff bristles on its acerose leaves, and by its aggregate flowers.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

*** *Herbaceous, with yellow Flowers.*

24. *Gnaphalium Cylindricum*. Leaves sessile, oblong, tomentose; corymbs unequal; calices smooth, cylindric, sessile; herb branched, diffuse, a span in length, tomentose all over.—Native of the Cape of Good Hope; cultivated in the same way as the first species.

25. *Gnaphalium Orientale*; *Eastern Everlasting*. Leaves linear, lanceolate, sessile; corymb compound; peduncles elongated; stem seldom rising more than three or four inches high, and putting out many heads; flower-stems eight or ten inches high, with narrow hoary leaves all the way, terminated

by a compound corymb of bright yellow flowers in large heads, coming out in May, and continuing in succession most part of the summer. It has been long in Portugal, where, in the winter season, they ornament the churches with the flowers. The shrubby or narrow-leaved variety grows naturally at the Cape of Good Hope. See the first and thirteenth species, for its propagation and culture.

26. *Gnaphalium Arenarium*. Leaves lanceolate, the lower ones obtuse; corymb compound; stalks quite simple. This is an annual hoary plant; stem upright, a foot or more in height, white with down. The shining yellow heads of flowers are two lines in length and breadth; the calicine scales are ovate, blunt, and lemon-coloured, as are also the corollets. It is supposed to preserve woollen clothes from the moth, and was formerly much recommended in dysenteries, but is now disused.—Native of Scania, Denmark, and Germany, where it is found in dry sandy pastures and hills, flowering from July to September; also of Japan, where it is used for moxa, and as tobacco, and is found by way-sides, and in ditches, flowering from December to April. This, with the rest of the European sorts, if the seeds are permitted to scatter, will come up with greater certainty than if they were sown; but they are rather regarded as weeds, than as garden plants.

27. *Gnaphalium Rutilans*; *Shining-flowered Everlasting*. Leaves lanceolate; corymb decomposed; stalk branched at bottom. The flowers are produced in a compound corymb at the ends of the branches; at their first appearance they are of a pale red, but afterwards change to a gold colour; the calices are small and dry, like the other species of everlasting.—Native of the Cape of Good Hope. It flowers from the end of June till August. This species is also to be treated in the same manner as the first.

28. *Gnaphalium Milleflorum*. Flowers corymbed, fastigiate, reddish white; calices subcylindric; stalk a foot high, tomentose; corollas yellow.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

29. *Gnaphalium Imbricatum*. Leaves lanceolate, tomentose; calicine scales reflex; stalk branched; branches alternate, wand-like, simple, tomentose, erect.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

30. *Gnaphalium Cymosum*; *Branching Everlasting*. Leaves lanceolate, three-nerved, smooth on the upper surface; raceme terminating; stalk branched at bottom. The flowers are entirely of a gold colour, and smooth, with blunt scales; they are very numerous, small, and oblong, and, like the leaves, emit, when rubbed, an odour like that of southernwood.—It flowers from April to August, and is a native of the Cape of Good Hope. For its propagation and culture, see the first species.

31. *Gnaphalium Nudifolium*. Leaves lanceolate, three-nerved, naked, with netted veins; stalk simple, a foot high, having smaller leaves of a more lanceolate shape at bottom, and naked at top; flowers golden, in a compound corymb; root-leaves lanceolate, ovate, by no means tomentose, scabrous about the edge. Perennial.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

32. *Gnaphalium Luteo-album*; *Jersey Everlasting*, or *Cudweed*. Leaves half stem-clasping, sword-shaped, repand, obtuse, pubescent on both sides; flowers conglomerate. This is an annual plant, and very woolly; stalks many, upright, a foot or eighteen inches in height. It flowers from July till September.—Native of the south of France, Spain, Portugal, Switzerland, Germany, the island of Jersey, the

sea-coast of Wales, the west of England, and found near Bosnor rocks in Sussex, and in sandy grounds, or on dry banks and walls; observed also in New Caledonia. This will come up better from scattered seeds, than when they are sown by art; but if the seeds be sown, it must be soon after they are ripe. The plants require only to be kept clean from weeds, and to be thinned where they are kept too close.

33. *Gnaphalium Albescens*. Snowy tomentose: leaves linear, lanceolate; stalk upright, undivided at bottom; branches terminating, fastigiate; flowers crowded, conical, shrubby, and a native of Jamaica. Cultivated like the first species.

34. *Gnaphalium Pedunculare*. Leaves spatulate, somewhat stem-clasping, tomentose underneath; calicine scales sharpish; stalk herbaceous, a foot and a half in height, branched, diffused, with elongated branches.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

35. *Gnaphalium Odoratissimum*; *Sweet-scented Everlasting*. Leaves decurrent, mucronate, tomentose on both sides, flat; stems terminated by a compound corymb of flowers, closely joined together, of a bright gold colour, but small, and changing to a darker colour as they fade.—Native of the Cape of Good Hope. Cultivated like the first species.

**** *Herbaceous, with white Flowers.*

36. *Gnaphalium Sanguineum*. Leaves decurrent, lanceolate, tomentose, flat, with a little naked point at the end; stems about six inches high, with lanceolate-acute leaves, woolly, terminated by a large corymb of flowers, sitting very close, and of a fine red colour.—Native of Egypt and Palestine. See the thirteenth species.

37. *Gnaphalium Fœtidum*; *Strong-scented Everlasting*. Leaves stem-clasping, quite entire, acute, tomentose underneath; stalk branched. This is an annual plant, sending out many oblong blunt leaves near the root; stems terminated by a corymb of flowers, which have large silvery calices, that will retain their beauty several years.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

38. *Gnaphalium Undulatum*; *Waved Everlasting*. Leaves subdecurrent, lanceolate, waved, acute, tomentose underneath; stalk branched. The flowers are in a terminating corymb; they are white, and appear in July. The whole plant has a disagreeable odour.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

39. *Gnaphalium Americanum*. Root-leaves lingulate-lanceolate, snow-white beneath; stalk simple, upright, tomentose; flowers spiked, and lateral, sessile, crowded. It is annual, and seldom rises above six or nine inches in height.—Native of Jamaica, in the coldest mountains of Liguanea. Cultivated in the same manner as the first species.

40. *Gnaphalium Crispum*; *Curled Everlasting*. Leaves stem-clasping, spatulate, tomentose; calices very obtuse, plaited, and waved, tomentose at the base; stalks simple, hardish, tomentose, throwing out small branches from the axils, which, as well as the whole plant, are very white. The corymbs are leafless.—Native of the Cape of Good Hope. It is propagated and cultivated in the same way as the first species.

41. *Gnaphalium Helianthemifolium*; *Dwarf Cistus-leaved Everlasting*. Leaves somewhat stem-clasping, lanceolate; corymbs compound; calicine scales somewhat plaited; stalks wand-like, branched, tomentose.—Native of the Cape of Good Hope. It is cultivated in the same manner as directed for the first species.

42. *Gnaphalium Squarrosum*. Leaves sessile, tongue-

shaped, tomentose; the inner calicine scales subulate, and bowed back; stalks ascending, simple, scarcely a foot high, very tomentose; flowers terminating, crowded.—Native of the Cape of Good Hope. Cultivated like the first species.

43. *Gnaphalium Stellatum*. Leaves sessile, lanceolate, villose; calices acute, flesh-coloured on the outside; stalks several, half a foot high; flowers glomerate.—Native of the Cape of Good Hope. Cultivated in the same manner as the first species.

44. *Gnaphalium Obtusifolium*, or *Polycephalum*; *Blunt-leaved Everlasting*. Leaves lanceolate; stalk tomentose, panicled; flowers glomerate, conical, terminating; stems single, about nine inches high; corollas yellow.—Native of Virginia, Pennsylvania, and New England.

45. *Gnaphalium Margaritaceum*; *American Everlasting*, or *Cudweed*. Leaves linear, lanceolate, acuminate, alternate; stalk branched at top; corymbs fastigiate; root perennial, creeping, and spreading far, so as to become a troublesome weed; stalks extremely downy, white. The flowering branches form a broad flat bunch; each branch contains numerous crowded heads, on short, branched, downy peduncles, but the middle ones sessile; scales of the calix bluntly ovate, white, not downy. A decoction of the flowers and stalks is used in America, to foment the limbs for pains and bruises. It flowers from July to September.—Native of North America, where it grows in vast quantities in uncultivated fields, glades, and hills, and is called *life everlasting*, because the silvery heads, properly dried, will keep their beauty long without changing. It is found also in Kamtschatka, and has been long known in the English gardens, though none of our old herbarists mention its being found wild in this island. It has been observed near Bocking in Essex, and in various parts of Wales. Both it and the next species will thrive almost any where, and are easily propagated by their creeping roots.

46. *Gnaphalium Plantagineum*; *Plantain-leaved Everlasting*. Runners procumbent; stalk very simple; root-leaves ovate, very large. From the main stalk come out runners, which take root in the ground; flowers in a terminating corymb, white, and small, appearing in June and July.—Native of North America. See the preceding species.

47. *Gnaphalium Dioicum*; *Mountain Everlasting*, *Cudweed*, or *Cat's-foot*. Runners procumbent; stalk quite simple; corymb simple; flowers divided; root woody, brown, strikes deep, throwing out a few fibres. The root-leaves form a thick tuft, and are oval at the extremity, tapering into a long footstalk; they are green, and slightly hairy above, beneath white, with a thick down; flowering-heads three to eight crown the stem in a close bunch, on short peduncles. It rarely happens that any ripe seed is produced, indeed plants that creep by the root are often sterile. It flowers in May and June.—Native of open downs in most parts of Europe. In England, it is found on Newmarket heath, and Gogmagog hills; on Canham heath, near Bury; Swaffham and Stratton heaths in Norfolk; in Cornwall, and Wales; on Bernack and Withering heaths; in the northern counties, and in Scotland.

48. *Gnaphalium Alpinum*; *Alpine Everlasting*. Runners procumbent; stalk quite simple; head leafless; flowers oblong; root perennial; root-leaves lanceolate, wedge-shaped, the upper surface green, smooth, and even, the under white, with a streaked nap, so that the edge, even of the upper surface, appears white.—Native of the Lapland Alps, and of Switzerland.

49. *Gnaphalium Indicum*. Leaves lanceolate; stalk very much branched, diffused; corymbs unequal; calices coloured

within. Perennial: flowers small; calicine scales ovate, brown, those surrounding the disk dilated, round, and white, so that the heads are brown, with a white crown.—Native of the East Indies and Cochin-china.

50. *Gnaphalium Purpureum*. Leaves lanceolate, naked; stalk erect, quite simple; flowers in lateral sessile spikes. They appear in summer and autumn.—It is an annual plant, and a native of Carolina and Virginia.

51. *Gnaphalium Denudatum*. Leaves spatulate, underneath snowy-white tomentose, smooth and even above; stalks prostrate, filiform, hardish, with alternate upright branches; corymb or umbel terminating, and very short; flowers peduncled; calix green, with a short white ray.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

*** Resembling *Filago*, herbaceous.

52. *Gnaphalium Sylvaticum*; *Wood Everlasting*, *English* or *Upright Cudweed*. Stalk quite simple, upright; flowers scattered. This is a biennial plant. In woods, one stem from twelve to eighteen inches high, generally grows from the root. In open ground, the root-leaves form a thick tuft, and from among them arise several shorter stems, sometimes not more than three inches high, at first often declining, but very soon ascending.—It flowers in August, and is a native of most parts of Europe. In Great Britain, it has been remarked at Norwood in Surry; on Hampstead heath, and in the woods adjoining; near Charlton, about Harefield; in Gambia park, Cambridgeshire; in Armingdale wood near Norwich; on Naseby-field and Thorp Malsor in Northamptonshire; in rough pastures near Fladbury in Worcestershire; on a sandy heath, a mile from Shiffnall, on the road to Wolverhampton; on the banks of the canal, in the parish of Cosely in Warwickshire; on the great island in Winandermere, and on the Highlands of Scotland, and in some parts of South Wales.

53. *Gnaphalium Spicatum*. Stems herbaceous, quite simple; flowers in whorls; leaves in bundles, linear, revolute; calicine scales scariose, ferruginous, shining, ovate, lanceolate.—Native of Egypt. Cultivated like the first species.

54. *Gnaphalium Verticillatum*. Stalk quite simple; flowers in whorls; leaves linear. The whole plant, and even the flowers, are ash-coloured.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

55. *Gnaphalium Oculus Cati*; *Cat's-eye Everlasting*. Stalk prostrate; leaves ovate; flowers glomerate, terminating, extremely villose; calix concealed by a very thick white nap; corollas small, surrounded by nap.—Native of the Cape of Good Hope. It is cultivated precisely in the same manner as the first species.

56. *Gnaphalium Pilosellum*. Leaves lanceolate, five-nerved, tomentose underneath; stalk naked; flowers in heads; scape twice as long as the leaves, hairy.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

57. *Gnaphalium Declinatum*; *Creeping Everlasting*. Leaves linear, lanceolate; the calices with a white lanceolate ray; stalks prostrate, filiform; flowers in a terminating, fastigiate, leafless corymb; florets many, in a small calix.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

58. *Gnaphalium Coronatum*. Leaves lanceolate; calices with a manifold roundish ray; flowers in corymbs, heaped; peduncles leafy.—Native of the Cape of Good Hope. For its propagation and culture, see the first species.

59. *Gnaphalium Supinum*; *Dwarf Everlasting*, or *Cudweed*. Stalk simple, procumbent; flowers scattered; root-

leaves in tufts, half or three quarters of an inch long, narrow, linear-lanceolate, slightly hairy above, downy beneath, but greenish.—It flowers in July and August, and is a native of the Swiss and Italian Alps, and the tops of the Highland mountains in Scotland.

60. *Gnaphalium Uliginosum*; *Marsh Everlasting*, or *Cudweed*. Stalk branched, diffused; flowers crowded, terminating; leaves elliptical, tapering into a long footstalk, slightly downy and greenish above, more so and whitish beneath. The ends of the branches are crowded with numerous heads, of nearly sessile flowers, which appear in August.—Native of marshy places in most parts of Europe.

61. *Gnaphalium Glomeratum*; *Cluster-flowered Everlasting*. Stalk diffused; inner scales of the calices subulate and naked; leaves somewhat stem-clasping. Annual.—Native of the Cape of Good Hope. Cultivated like the first species.

62. *Gnaphalium Japonicum*. Herbaceous; upright leaves linear, sword-shaped, snowy-white underneath; heads terminating; root fascicled, with small fibres. Annual: stalks one or two, simple, naked at top, white with down, a span and a half in height; flowers on the stalk terminating, glomerate, sessile, purplish; the heads the size of a large pea.—It flowers in August, and is a native of Japan. Cultivated in the same manner as the first species.

63. *Gnaphalium Trinerve*. Shrubby; leaves sessile, lanceolate, three-nerved, snow-white underneath; heads terminating.—Native of New Zealand, and cultivated in the same manner as the first species.

64. *Gnaphalium Lanatum*. Herbaceous, woolly; leaves linear-oblong, callous, mucronate at the tip; corymb contracted; stalk very simple.—Native of New Zealand, and cultivated exactly in the same manner as the first species.

65. *Gnaphalium Involutum*. Herbaceous; leaves linear, elongate, mucronate, tomentose underneath; head terminating, leafy.—Native of New Zealand. Cultivated in the same way as the first species.

66. *Gnaphalium Sinuatum*. Herbaceous; branches assurgent; leaves ovate-lanceolate, sinuate, toothed, hairy on both sides; stem four feet high, simple, erect; flowers yellow, in terminating erect panicles; the marginal scales of the calix being red, and membranaceous.—Native of Cochin-china. Cultivated like the first species.

Gnetum; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Ament* of whorls: remote, callous, thickened, propped underneath with a partial calicle. This is peltate, orbicular, flat, quite entire, and contains sessile floscules; the males at bottom, the females above in the same whorl. *Males*. *Calix*: scale ovate, minute-coloured. *Corolla*: none. *Stamina*: filamentum single, filiform, longer than the scale; antheræ double, connected. *Female*. *Calix*: scale torn, rude. *Corolla*: none. *Pistil*: germen ovate, immersed in the receptacle of the whorl, the length of the stamina; style conic, short; stigma trifid, acute. *Pericarp*: drupe ovate, one-celled. *Seed*: nut oblong, streaked. *Observe*. Rumphius has determined it to be dioecous. ESSENTIAL CHARACTER. *Male*. *Ament*, with scales. *Corolla*: none; filamenta one, with two antheræ. *Female*. *Ament*, with scales. *Corolla*: none; style with a bifid stigma. *Drupe*: with one seed.—The only known species is,

1. *Gnetum Gnemon*. Branches stiff-jointed, broader below the joints; leaves opposite, petioled, lanceolate, ovate, quite entire, smooth, and even; aments axillary, peduncled, in pairs from each axil, in small whorls, from an orbicular, perfoliate, entire bracte, callous above, in which the floscules are immersed; the females above, or towards the rachis,

appearance of the second species, and is suspected to be a variety of it.

13. *Gorteria Barbata*; *Bearded Gorteria*. Leaves elliptic, lanceolate; tooth awned; calices peduncled, ciliate-setaceous; stems diffused, simple, white, tomentose; peduncle terminating; very long, leafless, putting off a white nap, one-flowered. The outer order of leaflets in the calix is of the same form with the leaves; the inner is coloured, more copious, narrower, and ends in an abundance of bristles, that are twice as long as the flower.—Native of the Cape of Good Hope.

Gorze. See *Ulex*.

Gossypium; a genus of the class Monadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth double; outer one-leaved, trifid, flat, larger; inner one-leaved, bluntly emarginate, in five rows, cup-form. *Corolla*: petals five, obcordate, flat, spreading, fastened by their base to the tube of the stamina. *Stamina*: filamenta numerous, uniting at bottom into a tube, separate at, and below the tip, lax, inserted into the corolla; antheræ kidney-form. *Pistil*: germen roundish; style columnar, the length of the stamina; stigmas three or four, thickish. *Pericarp*: capsule roundish, acuminate; three or four-celled; partitions contrary. *Seeds*: very many, oval, involved in cotton. **ESSENTIAL CHARACTER.** *Calix*: double; outer trifid. *Capsule*: four-celled. *Seeds*: wrapped in cotton. The cotton plants will not endure the open air in England.—The species are,

1. *Gossypium Herbaceum*; *Common Cotton*. Leaves five-lobed, without glands underneath; stem herbaceous; root tapering, woody, with numerous fibres; annual; seed-lobes two, kidney-form, terminating gradually in a long petiole, with the figure of a halved funnel; calix outer, when closed three-cornered, when open, three-parted almost to the base; segments heart-shaped, gashed, shorter by half than the corolla, dotted with black; inner cylindrical, only one-third of the others' length, upright, five-parted, with short blunt segments, dotted like the inner; corolla monoepetalous, with a very short tube, and a five-parted spreading border; the segments blunt, crenate at the side, pale yellow, with five red spots at bottom, and deciduous; filamenta coalescing into a pyramid; germen superior, ovate; style filiform; stigma four-fold; capsule bluntly three-cornered, three-valved, three-celled; seeds ovate, about three in each cell, convex on one side, more flat on the other, immersed in fine cotton. Few plants are more useful, since it furnishes materials for clothing in the four quarters of the world, particularly to the Asiatics. The seeds also are an article of food, and esteemed wholesome. This is the common Levant cotton, which is cultivated also in several islands of the Archipelago; and in Malta, Sicily, and the kingdom of Naples; as well as in most parts of Asia. Both this and the third species will ripen their seeds in England, if they be sown upon a good hot-bed early in the spring. When the plants come up, they must be removed into separate pots, and plunged into the bark-bed to bring them forward: when they are too tall to remain under the frames, remove them into the tan-bed in the stove; and when the roots have filled the pots, remove them into larger. With this management, the flowers will appear in July, and the seeds ripen towards the end of September. The shrub cotton will rise from seeds very easily, if sown on a good hot-bed early in the spring; if they be brought forward in the same manner as directed for the others, the plants will be five or six feet high in the same summer; but it is difficult to preserve them through the winter, unless they are hardened gradually during the warm weather; for when they are forced on at that time, they will

become so tender, as to be incapable of resisting the least injury. In autumn, they must be placed in the bark-stove, and kept in the first class of heat, otherwise they will not live through the winter in England. Cotton is propagated in the West Indies by the seed, which is set in rows, about five feet asunder, at the end of September, or beginning of October; at first but slightly covered; but after it is grown up, the root is well moulded. The seed is subject to decay when it is set too deep, especially in wet weather. The soil should not be stiff, nor shallow, because this plant has a tap-root. The ground is hoed frequently, and kept very clean about the young plants, until they rise to a moderate height, otherwise they are liable to be destroyed by caterpillars. It grows from four to six feet high, and produces two crops annually; the first in eight months from the time of sowing the seed, the second within four months after the first; and the produce of each plant is reckoned about one pound weight. The branches are pruned or trimmed after the first gathering; and if the growth be over luxuriant, this should be done sooner. When great part of the pods are expanded, the wool is picked, and afterwards cleared from the seeds by a machine, called a gin, composed of two or three smooth wooden rollers, of about one inch diameter, ranged horizontally, close, and parallel to each other in a frame; at each extremity, they are toothed or channelled longitudinally, corresponding one with the other; and the central roller being moved with a treadle or foot-lath, resembling that of a knife-grinder, makes the other two revolve in contrary directions. The cotton is laid in small quantities at a time, upon these rollers, whilst they are in motion; and readily passing between them, drops into a sack, placed underneath to receive it, leaving the seeds, which are too large to pass with it, behind. The cotton, thus discharged from the seeds, is afterwards hand-picked, and cleansed thoroughly from any little particles of the pods or other substances, which may be adhering to it. It is then stowed in large bags, where it is well trod down, that it may lie close and compact; and the better to answer this purpose, some water is every now and then sprinkled upon the outside of the bag; the marketable weight of which, is usually three hundred pounds. An acre may be expected to produce, from two hundred and forty pounds, to that quantity; or two hundred and seventy pounds on an average.

2. *Gossypium Arboreum*; *Tree Cotton*. Leaves palmate, with lanceolate lobes; stem shrubby, eight feet high, the thickness of the human leg, with a rugged brown bark, and long, diffused, twisted branches; flowers entirely yellow, terminating, solitary; outer calix three-leaved, large, gashed, erect; the inner calix five-notched; capsule commonly three-cornered, three-valved, three-celled, subovate, acuminate, rugged.—Native of the East Indies.

3. *Gossypium Hirsutum*. Leaves five-lobed, with one gland underneath; the twigs and petioles pubescent; stem shrubby, a fathom in height, erect, striated; branches hirsute; petioles round, striated, dotted with black, hirsute. There is a single glandular pore on the mid-rib underneath, and sometimes two or three on the next nerves; peduncles three times shorter than the petioles, stiff, thick, hirsute, dotted with black; outer calix three or five cleft; the segments ovate, acute, rough with hairs; the inner truncate, with three blunt teeth; petals rounded, retuse, entire, yellow at the base, purple at the tip, pubescent on the outside; germen ovate, acuminate, dotted with black; style longer than the stamina, three or five-cleft at top, inclined. This species, says Browne, is in a few gardens in Jamaica, but is not much cultivated; for the cotton is not thought to be so

good; and the seeds are so small, that it is a difficult matter to separate them from the cotton. It grows, however, more luxuriant than the common sort, and rises generally from seven to nine feet high, bearing a great number of seed-vessels on all the branches. Swartz mentions a variety of this species, which is called *cotonier de soie*, the cotton of which is better than any of the rest.

4. *Gossypium Religiosum*; *Spotted bark Cotton Tree*. Leaves three-lobed, acute, with one gland underneath; twigs spotted with black. According to Swartz, the stem is a fathom in height, biennial, roundish, rugged; branches spreading very much, angular, striated; upper leaves three-lobed, lower five-sided; lobes ovate, entire, nerved, pubescent, with three glandular pores underneath, on the mid-ribs of the leaves; petioles long, round, patulous, hirsute, with black atoms scattered over them; flowers opposite to the petioles, large, fulvous, on short dotted peduncles; outer calix subtriphyllous, pubescent, dotted; the segments large, deeply and unequally toothed; the inner is very short, and five-lobed, in waves; capsule leathery, thickish, three-celled, three-valved; the partitions inserted in the middle of the valves, which are wrinkled within, and the edges turn back after they are open. There is no receptacle, but the seeds are fixed in a double row to the central angle of the cells; seeds about six in each cell, ovate, tapering towards the umbilicus, convex on one side, angular on the other, and white. It flowers in July.—Native of India, China, and the Society Isles; also cultivated in Jamaica.

5. *Gossypium Latifolium*. Leaves acute, the lowest undivided, the rest three-lobed, with one gland underneath; stem four or five feet high, perpendicular, round, straighter at the base, the thickness of a swan's quill; above flexuose and thicker, somewhat angular, swelling at the origin of the branches, green, rugged, pubescent, branched; flowers solitary, commonly one only on each branch; peduncle short, three-sided, opposite to the leaf. The stem-branches, petioles, peduncles, young leaves, and smaller veins, of those which are more advanced, are dotted with black. The calix also is dotted; the outer three-leaved, and also three-sided; the leaflets cordate, lacinated; the segments lanceolate, converging; the inner only one-third of the length, urceolate, striated, five-parted, with short acuminate segments; corolla as large as that of the hollyhock, white, turning red as it withers, without any spots at the base, where it is hirsute; pistil longer than the stamina; seeds in each cell four to six or more, in a double row, involved in very white cotton. Cultivated in the West Indies.

6. *Gossypium Barbadosense*; *Barbadoes Cotton Tree*. Leaves three-lobed, quite entire, with three glands underneath; stem from six to fifteen feet in height, suffruticose, biennial, smooth; branches almost erect, round and smooth, or pubescent; petioles five or six inches long, roundish, patulous, smooth, or sometimes pubescent, one-flowered; flowers large, yellow, finally turning red; outer calix half five-cleft; segments acute, smooth, or pubescent, or having black atoms scattered over them; inner having three or five minute blunt teeth; petals having a purple spot at the base, and smooth on the outside; filaments shorter than the petals; antheræ yellow or fulvous; germen roundish, acuminate; style three or five-cleft at top; capsule ovate, roundish, smooth, sometimes dotted with black, three-celled, three-valved; seeds oblong, eight to twelve, black, easily separated from the cotton. Swartz informs us, that this, and the third and fourth species, are not easily distinguished; for they vary in the size of the parts, the division and pubescence of the leaves, the colour, adherence, and tenacity of

the cotton, and the number of glands at the back of the leaves; so that it is difficult to ascertain which are species, and which are varieties. This, however, is the species which is so much cultivated in the West Indies, and forms a considerable branch of their exports. See the description of the method of cultivation under the first species. An emulsion of the seeds of this plant, is recommended in the bloody flux; and an oil is obtained from them by expression, which supplies the boiling-house lamps in some plantations.

Gouania: a genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodites*. *Calix*: perianth one-leaved, superior, funnel-form, five-cleft; tube permanent; segments ovate, acute, spreading, deciduous. *Corolla*: none. *Stamina*: filamenta five, subulate, length of the calix, and alternate with the segments; antheræ roundish, incumbent, veiled; veil like a cowl, elastic. *Pistil*: germen inferior; style subulate, half three-cleft; stigmas obtuse. *Pericarp*: fruit dry, three-sided, divisible into three seeds. *Seeds*: three parts of the fruit roundish, inclined to three-sided, two-winged. *Males*. *Calix*, *Corolla*, and *Stamina*: as in the hermaphrodites. *Pistil*: germen none; style as in the hermaphrodites; stigmas obscure or none. ESSENTIAL CHARACTER. *Hermaphrodites*. *Calix*: five-cleft. *Corolla*: none. *Antheræ*: five, under a veil. *Style*: three cleft; fruit inferior, tripartite. *Male*: similar, but without germen and stigma.—The only known species is,

1. *Gouania Domingensis*; *Chaw Stick*. Stem shrubby, and climbing like hops by axillary tendrils; leaves ovate or oblong-ovate, acuminate, or blunt, with a point, unequally serrate-toothed, or slightly crenate only, smooth, deep green, alternate, petioled, two inches long; racemes furnished with one or two leaflets. The male flowers have no pistil whatsoever; but there are three or four flowers in a hundred, that have a style without any germen.—Native of woods in St. Domingo. Sow the seeds on a hot-bed, early in the spring; and when the plants are strong enough, transplant each into a small pot filled with light rich earth, and plunge the pots into a moderate hot-bed of tanner's bark, watering and shading the plants until they have taken new root. In winter, plunge them into the bark-bed in the stove, and water them frequently. The stems must be supported, and they seldom produce flowers before the third summer.

Grafting, is the taking a shoot from one tree and inserting it into another, in such a manner, as that both may unite closely, and become one tree; this is called, by the ancient writers in husbandry and gardening, *incision*, to distinguish it from inoculating or budding, which they call *inserere oculos*. The peculiar advantage of grafting is, that it enables us to propagate any curious sorts of fruit, so as to be certain of the kinds, which cannot be done by any other method; for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as are not worth cultivating; but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock or tree on which they are grafted, for though the grafts receive their nourishment from the stocks, yet their varieties are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken; the only alteration is, that when the stocks on

which they are grafted do not grow so fast, and afford a sufficient supply of nourishment to the grafts, they will not make half so much progress as they otherwise would have done, nor will the fruit they produce be so fair, and sometimes not so well flavoured. The shoots are termed cions or grafts, and in the choice of them the following directions should be carefully observed: 1. That they are shoots of the preceding year, for when older they never succeed well. 2. Always take them from healthy and fruitful trees, for if the trees from whence they are taken be sickly, the grafts very often partake so much of the parent distemper, as rarely to get the better of it, at least for some years; and when they are taken from young luxuriant trees, whose vessels are generally large, they will continue to produce luxuriant shoots, and are seldom so productive as those taken from fruitful trees, whose shoots are more compact, and the joints closer together: it will always be some years before the luxuriant grafts begin to produce fruit, even when managed with the greatest skill. 3. Prefer those grafts which are taken from the lateral or horizontal branches, to those from the strong perpendicular shoots, for the reasons before given. These grafts or cions should be cut off from the trees before the buds begin to swell, which is generally three weeks or a month before the season for grafting, therefore when they are cut off, they should be laid in the ground with the cut downwards, burying them half their length, and covering their tops with litter to prevent their drying: if a small joint of the former year's wood be cut off with the cion, it will preserve it the better, and when they are grafted, this may be cut off; for at the same time the cions must be cut to a proper length before they are inserted in the stocks, but till then the shoots should remain in their full length, as they were taken from the tree, which better preserves them from shrinking. If these cions are to be carried to a considerable distance, it will be proper to put their ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month or longer, but these should be cut off earlier from the trees, than those which are to be grafted near the place where the trees are growing. Having given directions for the cions and grafts, we next come to that of the stock, which is a term applied to the trees intended for grafting; these are either such old ones as are already growing in the places where they are to remain, whose fruit is intended to be changed, or young trees, which have been raised in a nursery for a supply to the garden; in the former case there is no other choice but that of the branches, which should be such as are young, healthy, well-situated, and have a smooth bark: if these trees are growing against walls, or espaliers, it will be proper to graft six, eight, or ten branches, according to the size of the trees, by which they will be much sooner furnished with branches again, than when a less number of cions are put in; but in standard trees, four, or at most six cions, will be sufficient. In the choice of young stocks for grafting, you should always prefer such as have been raised from the seed, and that have been once or twice transplanted: next to these are those stocks which have been raised from cuttings or layers, but those which are suckers from the roots of other trees, should always be rejected, for these are never so well rooted as the others, and constantly put out a great number of suckers from their roots, whereby the borders and walks of the garden will be always pestered with them during the summer season, which is not only unsightly, but they also take off part of the nourishment from the trees. If these stocks have been allowed a proper distance in the nursery where they have grown, the wood will be better ripened and more compact than those which have grown close, and have

been thereby drawn up to a greater height; the wood of these will be soft, and their vessels large, so that the cions grafted into them will shoot very strong, but they will be less disposed to produce fruit than the other; and when trees acquire an ill habit at first, it will be very difficult to reclaim them afterwards. Having directed the choice of cions and stocks, we have now to describe the operation; in order to which, the operator must be provided with the following tools: 1. a neat small hand-saw, to cut off the heads of large stocks; a good strong knife with a thick back, to make clefts in the stocks; 3. a sharp pen-knife, to cut the grafts; 4. a grafting chisel, and a small mallet; a wedge, to keep open the clefts in large stocks till the insertion of the graft; 6. bass strings, or woollen yarn, to tie the grafts with—and such other instruments and materials as will be necessary and suitable to the kind of grafting to be performed; 7. a quantity of clay, which should be prepared a month before it is used, and kept turned and mixed like mortar every other day; this is to be made after the following manner: Procure a quantity of strong fat loam, in proportion to the quantity of trees intended to be grafted, then take some new stone-horse dung, and break it in amongst the loam, and if you cut a little straw or hay very small, and mix amongst it, the loam will hold together the better; and if there be a quantity of salt added, it will prevent the clay from dividing in dry weather; these must be well stirred together, with the addition of water, as in making mortar. The whole mass should be hollowed like a dish, and filled with water, and kept every other day stirred; but it ought to be remembered, that it should not be exposed to the frost or drying winds, and the oftener it is stirred and wrought, the better. Of late years, some persons have made use of another composition for grafting, which they have found more effectually to exclude the air than the clay just described: this is composed of turpentine, bees-wax, and resin, melted together, which, when of a proper consistence, may be put on the stock round the graft, in the same manner as the clay is usually applied, and though it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay; and as cold will harden this, there is no danger of its being hurt by frost, which is very apt to cause the clay to leave, and sometimes fall off; and when the heat of summer comes on, this mixture will melt, and fall off without any trouble. In order to use this, there should be a tin or copper pot, with a conveniency under it to keep a very gentle fire with small coal, otherwise the cold will soon condense the mixture, but you must be careful not to apply it too hot, lest the heat should injure the graft. A person who is a little accustomed to this composition will apply it very fast, and it is much easier for him than clay, especially if the season should prove cold. There are various ways of grafting; we shall enumerate five of the principal. 1. *Grafting in the rind*, called also shoulder-grafting, which is only proper for large trees; this is termed crown-grafting, because the grafts are set in the form of a circle or crown, and is generally performed about the latter end of March, or the beginning of April. 2. *Cleft Grafting*, which is also called stock or slit-grafting; this is proper for trees or stocks of a lesser size, from an inch to two inches or more in diameter; this grafting is to be performed in the months of February or March, and supplies the failure of the escutcheon-way, which is practised in June, July, and August. 3. *Whip Grafting*, which is also called tongue-grafting; this is proper for small stocks of an inch, half an inch, or less diameter; this is the most effectual way of any, and which is most in use. 4. *Grafting by approach*, or *ablactation*. This is to be performed when the stock you would

graft on, and the tree from which you take your grafts, stand so near together, that they may be joined; this is to be performed in the month of April, and is also called in-arching, and is chiefly used for jasmines, oranges, and other tender exotic trees. 5. *Grafting in the root*, which is of later invention than any of the former ways, and in many circumstances may be an improvement of them all.—The season for grafting must be regulated by the weather: our climate is so uncertain in the spring, that it is better to defer it till the circulation of the sap is brisk, and the buds of the stocks are beginning to break into leaves, observing only, that the weak shoots of tender trees will not admit of being so long cut as the more hardy: it is indispensably necessary never to graft while it actually freezes or rains. We come next to the manner of performing the several ways of grafting: The first method, which is termed rind or shoulder-grafting, is seldom practised, except upon large trees, where either the heads or the large branches are cut off horizontally, and two or four cions put in, according to the size of the branch or stem; in doing this, the cions are cut flat on one side, with a shoulder to rest upon the crown of the stock, then the rind of the stock must be raised up, to admit the cion between the wood and the bark of the stock, which must be inserted about two inches, so as the shoulder of the cion may meet, and closely join the crown of the stock; and after the number of cions are inserted, the whole crown of the stock should be well clayed over, leaving two eyes of the cions uncovered therewith, which will be sufficient for shooting: this method of grafting was much more in practice formerly than at present; the discontinuance of it was occasioned by the ill success it was attended with, for as these cions were placed between the rind of the stock and the wood, they were frequently blown out by strong winds, after they had made large shoots, which has sometimes happened after five or six years' growth, so that whenever this method is practised, there should be some stakes fastened to support the cions, until they have almost covered the stock.—The next method is termed cleft or stock-grafting; this is practised upon stocks or trees of a smaller size, and may be used with success where the rind of the stock is not too thick, which would prevent the inner bark of the cion from joining that of the stock; this may be performed on stocks or branches, which are more than one inch in diameter: in doing of this, the head of the stock or branch may be cut off with a slope, and a slit made the contrary way in the top of the slope, deep enough to receive the cion, which should be cut sloping like a wedge, so as to fit the slit made in the stock, being careful to leave that side of the wedge which is placed outward much thicker than the other; and in putting the cion into the slit of the stock, there must be great care to join the rind of the cion to that of the stock, for if these do not unite, the grafts will not succeed: when this method of grafting is used to stocks which are not strong, it will be proper to make a ligature of bass, to prevent the slit of the stock from opening; then the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts, only leaving two eyes of the cions above the clay for shooting.—The third method is termed whip or tongue-grafting, which is the most commonly practised of any by the nursery men near London, especially for small stocks, because the cions much sooner cover the stocks in this method than in any other. This is performed by cutting off the head of the stocks sloping; then there must be a notch made in the slope towards the upper part downwards, a little more than half an inch deep, to receive the cion, which must be cut with a slope upward, and a slit made in this

slope like a tongue, which tongue must be inserted into the slit made in the slope of the stock, and the cion must be placed on one side of the stock, so as that the two rinds of both cion and stock may be equal, and join together exactly; then there should be a ligature of bass to fasten the cion so as that it may not be easily displaced; it should lastly be clayed over, as in the former methods.—The fourth sort of grafting, termed inarching, grafting by approach, or ablactation, is only to be performed when the stocks, which are designed to be grafted, and the tree from which the graft is to be taken, stand so near together, or may be brought so near together, as that their branches may be united; this method of grafting is commonly practised on tender exotic plants, and some other sorts which do not succeed by any of the former methods. In performing this operation, a part of the stock or branch must be slit off about two inches in length, observing always to choose a smooth part of the stock; then a small notch should be made down in this slit of the stock, in the same manner as has been directed for whip-grafting; then the branch of the tree designed to be inarched, should have a part slit off in like manner as the stock, and a slit made upward in this, so as to leave a tongue, which tongue should be inserted into the slit of the stock, observing not to join their rinds equally, that they may unite well together; then make a ligature of bass, to keep them exactly in their situation, and afterward clay this part of the stock over well, to keep out the air. In this mode of grafting, the cion is not separated from the tree until it is firmly united to the stock, nor is the head of the stock or branch which is grafted cut off till this time, and only half the wood pared off with a slope, about three inches in length, and the same of the cion or graft. This method of grafting is performed later in the season than the others; it is generally undertaken in the month of April, when the sap is flowing, at which time the cion and stock will join together, and unite much sooner than at any other season. The walnut, fig, and mulberry, will take by this method of grafting, and will not succeed by any other: there are also several sorts of evergreens, which may be propagated by this method of grafting; but all the trees which are grafted in this way are weaker, and never grow to the size of those which are grafted in the other methods; therefore this is rarely practised, but on those trees which will not take by any other method.—The fifth mode of grafting is performed by cutting the clean smooth roots of the stocks in pieces five or six inches long, and as large or a little larger than the graft; let them be whip-grafted, and tied together very close, so as to prevent the wet from affecting the wounded parts; and plant them so deep, that the graft, which should be four or five inches long, may be about half buried. By this method the grafts themselves will root, and preserve a nearer similitude of the tree from whence they were taken; nay, after two or three years the stock may be cut quite away, and the graft left to maintain itself. In practising this method, the grafts may be an inch or two longer than is directed for the others.—The next thing necessary to be known by those who would practise this art, is, what trees will take and thrive by being grafted upon each other. No correct directions have hitherto been given by any of the numerous writers upon this subject, whose works strangely abound with radical mistakes; but as it would swell this interesting article beyond all bounds, were all the sorts of trees which will take upon each other by grafting to be here enumerated; we shall only give such general rules as will be sufficient to ensure the success of those persons who observe them. All trees of the same genus, that is, which agree in their flower and fruit, will take

upon each other; for instance, all the nut-bearing trees may be safely grafted on each other, as may all the plum-trees, including also the almond, peach, nectarine, apricot, &c. which agree exactly in their general characters, by which they are distinguished from all other trees; but as many of these are very subject to emit large quantities of gum from those parts which are deeply cut or wounded, (for the tender trees of this kind, such as peaches and nectarines, are most subject to these gummy exudations,) it is found to be the safest way to have recourse to budding or inoculation: see *Inoculation*. All such trees as bear cones will do well upon each other, though they may differ as to one being evergreen, and the other shedding its leaves in winter, as is observable in the cedar of Libanus, and the larch-tree, which are found to succeed very well upon each other; but these must be grafted by approach, for they abound with a great quantity of resin, which is apt to evaporate from the graft, if separated from the tree before it is joined with the stock, by which they are often destroyed, as are also the laurel on the cherry, and *vice versa*. All the mast-bearing trees will also take upon each other, and those which have a tender soft wood will do well if grafted in the common way; but those that are of a firm contexture, and are slow growers, should always be grafted by approach. By strictly adhering to these rules, the operation will seldom miscarry when rightly performed at a proper season, unless the weather should prove very bad, as it sometimes happens, whereby whole quarters of fruit-trees miscarry; and it is by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air; for, being grafted upon stocks of the same sort which are hardy, the grafts are rendered more capable to endure the cold, as has been experienced by most of our valuable fruits now in England, which were formerly transplanted here from more southerly climates, and were at first too impatient of our cold to succeed well abroad, but have been, by budding or grafting upon more hardy trees, rendered capable of resisting our severest cold.

Grass, is a general name applied to those herbaceous plants that are employed in the feeding and fattening of cows, sheep, &c. It has been long since observed, in an able treatise on the grasses of this country, that much of our meadow and pasture land may be rendered infinitely more valuable than it is at present, by the introduction of some of the best grasses we possess. This opinion prevails among the more enlightened agriculturists of the present age, some of whom have endeavoured to excite the husbandman to collect and cultivate seeds of this sort, by writings fraught with the soundest reasonings; while others have endeavoured to attract him by the offers of well-directed premiums. Hitherto, however, neither the able arguments of the one, nor the liberal rewards of the other, have been found sufficient to induce the husbandman to deviate from the beaten track; and Mr. Stillingfleet, the author above alluded to, sensibly adds, "It is wonderful to see how long mankind has neglected to make a proper advantage of plants of such importance, and which, in almost every country, are the chief food of cattle. The farmer, neglecting to distinguish and select

grasses for feed, fills his pastures either with weeds, or bad and improper grasses; when, by making an easy experiment, he might, after some trials, ensure the introduction of the best and most productive grasses that his land would bear. At present, if a farmer wants to lay down his land to grass, what does he do? he either takes his seed indiscriminately from his own foul hay-rick, or sends to his next neighbour for a supply: by this means, besides a certain mixture of all sorts of rubbish, (which must necessarily happen,) if he chance to have a large proportion of good seeds, it is not unlikely but that what he intends for dry land may come from moist, where it grew naturally; and from the contrary. This is such a slovenly method of proceeding, that one can hardly believe it to be universal, yet it generally prevails with respect to all grasses, except the darnel-grass, and what in some few counties is known by the name of Suffolk-grass; and this latter instance is owing, it is believed, more to the soil than any care of the husbandman. Now, (continues he,) would the farmer be at the pains of separating, *once in his life*, half a pint or a pint of the different kinds of grass seeds, and take care to sow them separately; in a very little time he would have wherewithal to stock his farm properly, according to the nature of each soil, and might at the same time spread these seeds separately over the nation, by supplying the seed-shops." The number of grasses fit for the farmer, probably does not exceed half a score: and how small would be the trouble, and how great the reward, of such a task! Would not any one be looked upon as almost insane, who should sow wheat, oats, rye, peas, beans, vetches, buck-wheat, turnips, and seeds of all sorts, together? Yet this is perpetually done with respect to grasses, although it is both unprofitable and absurd. It is also asserted by Mr. Kent, that meadow and pasture land is oftener neglected than ploughed land, notwithstanding it generally admits of a much greater proportion of improvement. The best grasses cannot be collected at too great an expense; for he has seen a small spot of land in the middle of a large piece, which was laid down twelve or fourteen years since, upon an estate in Hertfordshire, by Mr. Stillingfleet, with some choice seeds, at the same time when the remainder of the field was laid down with common seeds; and this spot is considerably better than the rest. From these experiments, and his own observations, he is clearly of opinion, that any person who has land calculated for grass, may improve it by this method of laying it down, to a much greater degree than he can in the common way. Dr. Anderson has likewise observed, in the second volume of his *Essays*, that although it is probable that none of the grasses that have been hitherto cultivated by the farmer, are of the most proper kind for pasturage; yet there is little reason to doubt, but that many of the most valuable kinds for this purpose would admit of being cultivated with the same ease as some of those are with which we are well acquainted, if they were properly separated from others, and cultivated with equal care. But so long as we shall remain ignorant of the peculiar properties of each kind of grass, so as not to be able to distinguish the good from the bad, it is not surprising that we should remain firmly persuaded that nature alone can provide valuable pastures, and that age is so essentially necessary for bringing them to their ultimate perfection: for if we allow our fields to remain uncultivated, without having sowed them with any kind of grass seeds, it must ever happen that the seeds of such grasses as are brought by the wind or otherwise from the neighbouring fields, will there take root, and in time establish themselves. And as it may sometimes happen, that some of the most valuable pasture grasses may there abound; the field, in these cases, will become filled

with their seeds, and in due time may afford the most valuable pasture. But if bad kinds of grasses should abound in the neighbourhood more than the good, the field will naturally become filled with the seeds of these useless plants, many of which are hard and abiding; so that if the field be once filled with them, the pasture will of course be of little value, if it should be allowed to remain undisturbed for any length of time. Let the reader therefore consider, how numerous the circumstances are, that must accidentally concur together, before it is possible to receive a very fine field of pasture grass from the hands of nature alone; he will then perceive how improbable it is, that they should concur to produce their full effect in any one field whatever. There must be no roots of bad grasses, nor seeds of robust annuals, in the soil, when it is left out from tillage; and the seeds of the most valuable kinds of grasses must be in the neighbourhood, in such abundance as to fill the whole world sufficiently at once. Nor is this all, for as there is, no doubt, a considerable variety of valuable kinds of grass, some of which are naturally fitted to grow to perfection in one kind of soil, or upon that soil when in certain circumstances, while others would thrive best upon another soil, or upon that soil only in certain peculiar circumstances; it must so happen, that these very plants which are best adapted to the soil in the state it may be in at the time, should be found in abundance in the neighbourhood of the field. Neither must there be found near that any sort of robust quick-growing plant, the seeds of which, by being blown upon that field, might suddenly rush up and suffocate in their infancy these tender and valuable plants; nor must there be found any kinds of bad grass, that, by being established along with the good in any proportion, might tend to diminish the value of the pasture. Now let any one reflect on the infinite diversity these few particulars may admit of, and think how utterly impossible it is, that all the favourable circumstances, without any that are unfavourable, should concur in any one case; and he will acknowledge, that those who found their hope of obtaining the most valuable pastures only upon the fortuitous concurrence of all these circumstances, or who imagine that every pasture which is old must on that account of necessity be good, act in direct contradiction to the plainest dictates of reason and common sense. For although it should be allowed, that the grasses hitherto cultivated are not of the most proper sort for forming good pastures, and that therefore, on some occasions, much better natural pastures may be met with than could be formed by means of any of these; yet it by no means follows from thence, that if the farmer were perfectly acquainted with the value and distinguishing qualities of each kind of natural grass, and knew the soil and culture that best agreed with it, the most advantageous manner of rearing it, and every other particular relative to its respective economy, he might not perhaps have it in his power to form artificial pastures as much excelling the natural, as these last at present usually exceed the former; for were he possessed of the knowledge above supposed, he could at once fill the soil with the seeds of those valuable grasses, which he knew were best adapted to it, and thus effectually exclude the admission of every useless plant, or pernicious kind of grass, that might be brought from the neighbouring fields by the wind, or by other accidental causes. Let us, therefore, instead of contenting ourselves on all occasions with such pastures or grass lands as nature may afford, rather study to improve those that are indifferent, by endeavouring to obtain a knowledge of such plants as might afford the most valuable pasture, and cultivating these with assiduity and care. The inattention of the improving far-

mers of Great Britain, to this subject, has been unaccountable. In order to prevent the public from being imposed upon by specious accounts of new grasses, it is necessary strenuously to endeavour to discover what are the particular purposes for which any one plant could be deemed valuable, and in what respects it ceases to be of any value at all; for as there is no plant that can be alike useful on all occasions, if we lose sight of this most necessary distinction, it may often lead us to rear a particular plant for purposes which it was never fitted to answer; and our failure may cause it to be rejected, where it might prove extremely proper and beneficial. It is stated, that ray-grass continues to be the only grass, the seeds of which can be purchased, for the purpose of laying down meadow and pasture land: and every intelligent farmer knows how inadequate that grass is for such a purpose. Why, indeed, the *lolium perenne*, ray or rye grass, should originally have been made use of in preference to all the other grasses, cannot perhaps be satisfactorily accounted for. It probably owes its introduction to accident, or to its being a common grass, the seeds of which were easily collected, rather than to its being preferred from any investigation of its merits, compared with the others. However this may be, there appears to be no reason for excluding the others; for it would appear exceedingly improbable, that of upwards of a hundred grasses, taking the word *grass* in its strict sense, that are growing wild in this country, the Author of nature should have created only one, as suitable to be cultivated for pasturage or fodder. Since this period, however, most of the natural grasses have been cultivated for the purpose of affording seed, which may be procured genuine from many seedsmen in most places. Taking it for granted then, that there are other grasses superior in many respects to the ray-grass, this question naturally arises: How comes it, that they have not found their way into general use? To this it may be replied, that improvements in any science, especially in agriculture, are slow in their advances; and perhaps no class of men adheres more pertinaciously to old prejudices, than that respectable class of invaluable men, the farmers. The difficulty of distinguishing the grasses from each other, has, no doubt, been one grand obstacle: many of these plants are so much alike, that the most discriminating botanist is often at a loss to know some of them apart: there is also another cause, which may have operated against their introduction: grasses, as well as other plants, have been frequently recommended from a partial and limited observation of them, by persons who neither knew them well, as botanists or agriculturists, or who have recommended them merely to gain by the credulity of the public. But perhaps the chief reason has been, that persons, who might be expected to make the improvements, have not enjoyed the means of making the experiment, owing to the difficulty of obtaining such sorts of grass seeds as may be most suitable for the purpose. It appears, however, that in the herbage of good meadows or grass lands, there should be a combination of produce, batableness or feeding, and early growth. The first is, in most cases, the grand object of the agriculturist, since it is the quantity chiefly which enables him to pay his rent, and support his cattle: to obtain this, the judicious husbandman spares no expense in labour or manure. But it does not follow, that produce is to be attended to solely, or that, for its sake, we are to cultivate rough cock's-foot grass, meadow-sweet, and such coarse plants. Grasses which are recommended for being remarkably grateful to cattle, as the sheep's fescue-grass, or for the sweetness of their foliage merely, if found to be deficient in the grand article of produce, will never answer the farmer or grazier's purpose, since, to be a

good meadow, it must be productive. Cattle have undoubtedly their particular likings, with respect to food, in which, though we cannot properly judge of it, they should be sometimes indulged; but this practice must not be carried too far, for as the farmer cannot afford to feed his ploughmen on sucking pigs and poultry, neither can he generally indulge his cattle with the finer or more delicate hay or herbage. Besides, we do not know but that the most productive grasses may also be the most nutritious, or that cattle will not as eagerly eat the herbage or hay-may of the meadow fox-tail grass, as of the fine bent *agrostis capillaris*, and procumbent trefoil, or *trifolium procumbens*. Moreover, cattle are frequently known to thrive on food to which they are habituated by necessity, though, at first, they could scarcely be prevailed on to touch it. Persons, in making experiments, are very apt to conclude too hastily from the appearance which a plant assumes, on its being first planted or sown: the most insignificant vegetable will often make a great show, when its fibres have fresh earth to shoot into; but the trial comes, when the object of our experiment has been in a meadow or pasture several years, when its fibres, from long growth, are matted together, and it meets with powerful neighbours to dispute every inch of ground with it: if it then continue to be productive, it must have merit. We see that lucern, when left to itself, is soon overpowered; if we sow broad-leaved clover, which is most undoubtedly a perennial, the first year we shall have a great crop of clover; let this field be left to itself, and the clover, like the lucern, will yearly diminish, not because it is a biennial, as some have supposed, but because plants, hardier or more congenial to the soil, usurp its place: this shews then, that at the same time we introduce a good plant, that plant must also be a powerful one, able to keep possession, and continue to be productive. With regard to the second quality, or that of the cattle's thriving on the food they eat; this is undoubtedly of great consequence, and it is to be regretted, that our knowledge of the most nutritive herb is so limited: of those plants which have been cultivated, we are able to speak with some certainty; it is well known, that clover, lucern, saint-foin, tares, and several other plants, have a tendency to fatten cattle; but what grasses, or other plants, which have not been subjected to a separate cultivation, have this particular tendency, remains to be ascertained by experiment. But as leguminous plants, in general, are found to agree with cattle, we may reasonably conclude, that a certain quantity of them must be proper in pastures. Certain pastures are found to be more bateable or feeding than others; but whether this arises from their situation, or their particular produce, remains also to be discovered by further observation. Respecting the third quality, or the early growth of plants, as the farmers and graziers unitedly complain of the want of early herbage in the spring; those plants, therefore, which are found to put forth early foliage, and to be grateful to cattle, are deserving of great attention. As far as grasses are concerned, the sweet-scented vernal, the meadow fox-tail, the smooth and rough-stalked meadow grass, will effect all that can be expected from those of British growth; much, very much, however, will depend on seasons: if the winter be very severe, or north-easterly winds prevail in the spring, grassy herbage will be backward: to counteract the effects of such seasons, our pastures should be warmly situated, not drenched with moisture, sheltered by thick hedges, and divided into small inclosures; in short, a set of inclosures should be formed for this very purpose, where there is a prospect of its answering the designs of the cultivator. But where early pasturage is the desideratum, other plants, as

well as grasses, may deserve a place amongst them, as ribwort or rib-grass, *plantago lanceolata*, dandelion, *leontodon*, *faraxacum*, broad-leaved clover, *trifolium pratense*, with many others of the same kind. And as an early herbage, though it be valuable for pasturage, is no less so for hay; by the middle of May at furthest, a meadow of this sort would be fit for mowing, and the second hay-making might commence by the time that hay-making usually takes place in the country. We have sometimes thought, but perhaps the idea is too speculative, that we ought to have two sorts of meadow, one for hay, the other for pasture; that our hay meadow should consist entirely of grasses, and chiefly for this reason, that the hay would thereby be much sooner made, which is an object of consequence at all times, but particularly when the process commences in May. In June and July, the more powerful heat of the sun is able to extricate the thick leaves and stalks of the more succulent plants; but in the necessary prolongation of this business, the grasses must materially suffer. But for the purpose of pasturage, the farmer should be chiefly directed to such sorts of grasses as have the propensity of running to leaves, in preference to such as abound more in flower-stalks or stems. Experiment has proved, that extraordinary fertility arises from unusual circumstances concurring and favouring, in an uncommon degree, the growth of various grasses; consequently, in the forming and improving of grass lands, the most certain plan will be to cultivate the seeds of such grasses as may be most adapted to them, and afterwards sow them at proper seasons upon the lands, when they have been put into a condition suitable for their reception. The directions given for cultivating, and collecting the seeds of various grasses that have been found to be very productive, are as follows. If a piece of ground, which is neither very moist nor very dry, can be procured, it will answer for all the seeds; they may then be sown on one spot; but if such a piece cannot be obtained, they must be sown on separate spots, according to their respective qualities, no matter whether in a garden, a nursery, or a field, provided it be well secured and clean. Dig up the ground, level and rake it, then sow each kind of seeds thinly in a separate row, each row nine or twelve inches apart, and cover them over lightly with the earth; the latter end of August, or the beginning of September, will be the most proper time for this business. If the weather be not unusually dry, the seeds will soon vegetate; and the only attention they will require, will be careful weeding: in about a fortnight after their coming up, such of the plants as grow thickly together may be thinned, and those which are taken up transplanted, so as to make more rows of the same grass. If the winter should be very severe, though natives, yet as seedlings they may receive injury; therefore it will not be amiss to protect them with mats, fern, or by some other contrivance. Advantage should also be taken of the first dry weather in the spring, to roll or tread them down, in order to fasten their roots in the earth, which the frost generally loosens: care must still be taken to keep them perfectly clear from weeds. As the spring advances, many of them will throw up their flowering-stems, and some of them will continue to do so all the summer. As the seed in each spike or panicle ripens, it must be carefully gathered, and sown in the autumn; at which time, the roots of the original plants, which will now bear separating, should be divided and transplanted, so as to form more rows; the roots of the smooth-stalked meadow-grass, in particular, creeping like couch-grass, may readily be increased in this way; and thus, by degrees, a large plantation of these grasses may be formed, and much seed collected for the farmer's use. But a more

ready way, according to a late writer, is for the farmer to notice that species of grass most affected by his soil, and carefully to gather the seed from a piece of old meadow, purposely left three or four weeks longer than common, or at least long enough to become sufficiently ripe. He should not scruple the trouble of selecting the heads as they lie in the swathe; but they who desire not to be so particular, will thresh out the seed together, either in the field, or before it shall have been heated in the mow. Good seeds of different sorts of grasses may now also be procured from different seedsmen in large towns, and other places; but the collection, sold under the title of hay-seeds, should never be trusted to in any respect. Mr. Curtis, from the numerous applications that were made to him by gentlemen for grass-seeds, was induced to select such as appeared to him the most useful, and thereby rendered the public an essential service. He wished, at least, to put in their power to decide on a matter which had been long agitated, and which he was far from being the only one that entertained the sanguine hopes of its proving a great national advantage. The grasses he has recommended, will, he is confident, do all that our natural grasses can do: they are six of those which constitute the bulk of our best pastures; most of them are early, all of them are productive, and they are adapted to such soils and situations as are proper for meadows and pastures. They are, however, in common with other plants, liable to produce small or great crops, according to particular seasons, or to the fertility or barrenness of the soil on which they are sown and cultivated. The names of these grasses, with the order of their flowering, is as follows. 1. Sweet-scented vernal: 2. meadow fox-tail: 3. smooth-stalked meadow: 4. rough-stalked meadow: 5. meadow fescue: 6. crested dog's-tail. The meadow fox-tail, and rough-stalked meadow-grass, are fittest for moist land; the meadow fescue, or sweet-scented vernal, are the most proper for land, either moist or moderately dry; and the smooth-stalked meadow-grass, and crested dog's-tail, are those that are best suited for dry pastures, and other similar lands. Mr. Curtis observes, that many more grasses might be deservedly added to the above list, but expresses his doubts, whether by recommending more, he might not increase the difficulty of introducing grass-seeds, without any adequate advantage in return. We shall, however, subjoin a list of other grasses, which may be useful to those agriculturists who wish to obtain all possible information upon the subject. 1. *Avena elatior*, or tall oat-grass. It is early, very productive, affording a plentiful aftermath; and, for its excellence, approaches to the *alopecurus pratensis*, for which it may prove a good substitute: 2. *avena flavescens*, or yellow oat-grass; affecting dry soils; it is rather early, and tolerably productive: 3. *bromus mollis*, or south brome grass; this, as an early grass, might probably be cultivated to advantage, but, like other grasses, it sheds the seeds, and withers before the whole is ready for mowing: 4. *cynosurus coeruleus*, or blue dog's-tail grass; this is the earliest of all our grasses, but is neither productive nor of a good quality: 5. *dactylis glomeratus*, or rough cock's-foot grass; a rough, coarse, but extremely hardy and productive grass, common in orchards and meadows, and appearing rather early: 6. *festuca ovina*, sheep's fescue grass; native of dry elevated heaths and commons, unproductive, with a hard and wiry foliage; it grows to be only a small plant, even in a rich moist soil: 7. *hordeum murinum*, wall-barley grass, or squirrel-tail grass; common by walls, and the sides of paths. It is very injurious to horses, when mixed among their hay, by the awns or beards of the ears sticking in their mouths: 8. *hordeum pratense*, or meadow barley-grass; taller and more delicate,

sometimes forming great part of the crop in good meadows. It is neither very early, nor remarkably productive, and would probably be as injurious to horses as the preceding sort: 9. *holcus lanatus*, or meadow soft grass; hardy and productive, flowering a month later than the *anthoxanthum*, foliage soft and woolly: 10. *holcus mollis*, or creeping soft grass; it grows well in sandy soils, and bears drought: 11. *lolium perenne*, or ray-grass; wiry, with little foliage in upland pastures, but in rich meadows its foliage is abundant, and of rapid growth: 12. *poa annua*, or dwarf meadow-grass; perpetually flowering, and seeding most rapidly, unless prevented by cold, growing in almost any soil or situation, but never acquiring any great height; its foliage is tender and grateful to cattle, but liable to be killed by winter's frost, and summer's drought: 13. *phleum pratense*, or meadow cat's-tail grass; imported from America, under the name of Timothy grass. It is very productive in wet situations, but coarse in quality, and late in appearance, beside having no one excellence which *alopecurus pratensis* does not possess in an equal or superior degree: 14. *tritium repens*, creeping wheat-grass, quick, or couch-grass. Too well known to farmers and gardeners, as an early, but most troublesome weed.—*Grass for meadows and pastures.* The land on which grass-seed is intended to be sown, should be well ploughed, and cleared from the roots of noxious weeds, such as couch-grass, fern, rushes, heath, gorse, broom, restharrow, &c. which, if left in the ground, will soon get the better of the grass, and overrun the land. Therefore, in such places where any of these weeds abound, it will be a good method to plough up the surface in April, and let it lie some time to dry; then harrow the roots into small heaps, and burn them. The ashes so produced, when spread on the land, will be a good manure for it; but where couch-grass, fern, or restharrow is in plenty, the land must be twice or thrice deeply ploughed in dry weather, and the roots carefully harrowed off after each ploughing, which is the surest means of destroying them: where the land is low, and of a stiff clayey nature, which holds water in winter, it will be of singular service to make some underground drains, to carry off the wet, which, if detained too long on the ground, will turn the grass sour. The method of making these drains is described under the article *Meadow*; which see. Before the seed is sown, the surface of the ground should be made level and fine, otherwise the seed will be buried unequally. When the seed is sown, it must be greatly harrowed in, and the ground rolled with a wooden roller, which will smooth the surface, and prevent the seeds from being blown into patches. When the grass comes up, if there should be any bare spots where the seed has not grown, they may be sown again, and the ground rolled, which will fix the seeds, and the first kindly showers will bring up the grass, and make it very thick. Where the land is designed to continue in pasture, it should be sown with the best sorts of grass seeds, and white Dutch clover, or what is commonly called honey-suckle grass in many parts of England; but there is a great difficulty of procuring good seeds, which can only be removed by selecting the best sorts in the manner already described; for in all the good pastures near London, which abound with the best sorts of grass, the hay is commonly cut before the seeds of the grass are ripe; so that those seeds which are procured from the stables where the horses are fed with the best sort of hay, are little more than chaff, or at best are only such as are of the early kinds of grass, with a great quantity of plantain, and other weeds, which has discouraged many gentlemen from sowing them: and as it requires more time and attention to collect a sufficient quantity

of the purer sorts of grass-seeds, we would recommend those who will not, or cannot, make that profitable experiment, which we have endeavoured to describe in the former part of this article, to set some of those upland pastures, which are least infested with weeds, and afford the sweetest herbage, aside to stand for seeds; and although, by so doing, the hay will be less valuable, yet from the sale of the seeds, it may answer better to the possessor, than to mow it merely for the hay; for any gentleman, who has regard to the beauty of his land, had better pay six times the price for even such seeds as these, rather than purchase the ordinary sort; for the first cost of seeds is not to be put in competition with the beauty and advantage of having such as are good; which, when the land is brought to a good sward, which may be done in one year, where it is properly prepared and sown, may be easily kept in good order, and annually improved by good management, so as to last as long as that good management continues. Forty years ago, some land was sown in the following manner, and affords to this day the most excellent pasture. It abounded with many bad weeds, so that it became necessary to give a summer and winter's fallow; during which, it was five times ploughed, and ten times harrowed, to destroy the weeds, and make the surface of the ground fine. In August, it was sown with the best grass-seeds that could be procured, three bushels of which, with nine pounds of the white Dutch clover-seeds, were allowed to each acre: as there happened rains soon after the seed was sown, the grass came up well, but mixed with a great number of weeds: it was afterwards rolled; and that summer, there was more than two tons of hay per acre mowed off the land; and by constant weeding twice a year, sweeping it with a brush harrow, rolling and dressing of the land, the grass has been since greatly improved, and is now as good a pasture as any in England. Large tracts of land laid down in the same manner have succeeded equally well; so that many years' experience, upon an extended scale, confirms this to be the surest means hitherto adopted, for obtaining good pastures. The generality of farmers, to whom this plan is proposed, will object to the first loss of their crop, and also to the after expense of weeding, rolling, &c. as too great for common practice. Long experience, however, on the contrary, testifies, that whoever will be at the expense, will find their account in it; for the crops of hay will be so much better, and the after pasture also, that it will more than pay the expense; and the verdure of these pastures is delightful to all those who have any taste for natural beauties.—*Grass for gardens.* The English grass is of so good a quality for walks or grass-plats, that if they be kept in good order, they have that exquisite beauty, which exceeds those of France, or any other country. But green walks and green plats are not generally made by sowing the grass-seed, but by laying turfs; and, indeed, the turfs from a fine common or down, are for that purpose, much preferable to sown grass. In sowing a fine green plat, there is a difficulty in getting good seed; it ought not to be such as is taken out of the hay-loft without distinction; for that seed shooting too high, and making large stalks, the lower part will be naked and bare; and, however frequently moved, will come to nothing but tufts of weeds and quick-grass, very little better than that of the common fields. If walks or plats be made by sowing, the best way is to procure the seed from those pastures where the grass is naturally fine and clear, or else the trouble of keeping it from spiry and bent grass will be great, and it will hardly ever look handsome. In order to sow grass seed, the ground must be first dug or broken up with a spade; and when it has been dressed and laid even, it must be very finely

raked over, and all the clods and stones taken off, and covered over an inch thick with good mould, to facilitate the growth of the seed; this being done, the seed is to be thrown pretty thick, that it may come up close and short; and it must be raked over again, to bury and cover the seed, that if the weather should happen to be windy, it may not be blown away. As to the season of sowing grass, the middle or latter end of August is a good time, because the seed naturally requires nothing but moisture to make it grow; if it be not sown till the latter end of February, or the beginning of March, if the weather prove dry, it will not so soon make the walks or quarters green. It is also best to sow it in a mild day, and inclining to rain; for that, by sinking down the seed in the earth, will cause it to shoot the sooner. But where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the white trefoil, or Dutch clover, sown with it; for this will make a fine turf much sooner than any other sown grass, and will retain a better verdure than any of the grass tribe. After the seed is well come up, and the grass is very thick, and of a beautiful green, it will require a constant care to keep in order: this consists in mowing the grass often, for the oftener it is mowed, the thicker and handsomer it grows; it must also be rolled with a cylinder, or roller of wood, to level it as much as possible. If grass be neglected, it will run into quick-grass and weeds, and then the only way to recover it, is either by sowing it, or laying it over again, and that once in every two years; but if the ground be well cleared from the roots of strong weeds, and the turf taken from a fine level common, it will continue handsome for several years, provided it be well kept. In order to keep grass-plats or walks handsome, and in good order in autumn, you may sow some fresh seeds over any places that are not well filled, or where the grass is dead, to renew and furnish them again; but there is nothing which so much improves grass, as the constantly rolling and polling it, to destroy worm-casts, and refine the turf. It is a general practice, when turf is laid in gardens, to cover the surface of the ground under the turf, either with sand or very poor earth; the design of which is, to keep the grass fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not so for such ground as is middling or poor; for the grass will soon wear out, and decay in patches. When turf is taken from a common or down, there should be regard had to the cleanliness of it; such as is full of weeds should be rejected, for it will be a very tedious task to weed them out after the turf is laid; and unless this be done, the grass will never appear handsome. Where turf is designed to remain for years, without renewing, there should be a dressing laid upon it every other year, either of very rotten dung, ashes, or, where it can be easily procured, very rotten tan. These dressings should be laid on early in winter, that the rain may wash them into the ground before the drought of the spring comes on; otherwise they will occasion the grass to turn when the warmth of summer begins. Where grass is well dressed, and kept well rolled and mowed, it may be kept very beautiful for many years; but where it is neither dressed nor fed with sheep, it will rarely continue handsome more than eight or ten years. The grasses so extensively useful in rural economy, are chiefly to be found in the second order of the third class of the sexual system. However numerous and distinct from each other they may be, they generally agree in the following particulars, which form, when taken together, the natural character of this tribe or family. The calix is a glume or chaff in most species, composed of two valves, one larger and gibbous, the other smaller and

flat; the corolla is also a bivalve glume, and is accompanied by a very small, superior, two-leaved nectarium, of an oblong form; the stamina are three in number; the filamenta capillary; the antheræ oblong and bicapsular; there are two pistils, which are pubescent, reflex, or bent back from each other, and terminated by pubescent stigmas; one seed only, or grain, succeeds to each flower; it has no pericarp, but is covered by the calix, corolla, or both; it is of an oblong form, drawn to a point at both ends, and monocotyledonous, or composed of one lobe only. Besides this agreement in the fructification, although grasses are exceedingly difficult to distinguish from each other, they are known at first sight from all other plants, owing to their peculiar appearance or *habit*, as botanists have agreed to term it. Persons totally unskilled in botany can easily distinguish them; their stalk is simple or unbranched, straight, hollow, and jointed; their leaves are quite entire, of a long linear shape, acuminate, or drawing gradually to a point at the end, marked with lines parallel to the midrib or middle nerve; upon the culm or stalk there is only one of these leaves to each joint, arising from a sheath which invests the stalk, usually to a considerable distance; the seed, it is well known, is farinaceous, or abounding in meal, and is the principal food of many tribes of birds, as the seeds of the larger sorts, which we call corn, are of mankind. One genus of grass, the *anthoxanthum*, differs from the rest, in having two stamina only; and there are several genera, which, having male flowers mixed with the hermaphrodites, are placed by Linneus in his class Polygamia. All the grasses are particularly treated of under their respective genera and species, for which see *Ægilops*, *Agrostis*, *Aira*, *Alopecurus*, *Anthropogon*, *Anthisteria*, *Anthoxanthum*, *Apluda*, *Arundo*, *Avena*, *Bromus*, *Cenchrus*, *Crypsis*, *Cynosurus*, *Dactylis*, *Elymus*, *Eriophorum*, *Festuca*, *Holcus*, *Hordeum*, *Ischæmum*, *Lolium*, *Melica*, *Miegia*, *Milium*, *Nardus*, *Panicum*, *Pappophorum*, *Paspalum*, *Perotis*, *Phalaris*, *Phleum*, *Poa*, *Rottboellia*, *Saccharum*, *Secale*, *Stipa*, and *Triticum*.

Grass, Arrow-headed. See *Triglochin*.

Grass, Artificial. The grasses vulgarly called artificial, are mostly leguminous plants, totally different in every respect from grasses, except in being used as food for cattle; they belong to the class Diadelphia. See *Hedysarum*, for *Saintfoin*; *Medicago*, for *Lucerne*; and *Trifolium*, for *Clover* and *Trefoil*.

Grass, Barley. See *Hordeum*.

Grass, Bent. See *Agrostis*.

Grass, Wheat. See *Triticum*.

Grass, Wrack. See *Zostera*.

Gratiola; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, upright; segments awl-shaped, permanent. *Corolla*: monopetalous, unequal; tube longer than the calix; border four-parted, small; the upper segment broader, emarginate, reflex, the rest straight, equal. *Stamina*: filamenta four, awl-shaped, shorter than the corolla, the two lower shorter than the others, and barren, the two upper fastened to the tube of the petal; antheræ roundish. *Pistil*: germen conic; style straight, awl-shaped; stigma two-lipped, after fecundation converging. *Pericarp*: capsule ovate-acuminate, two-celled, two-valved. *Seeds*: very many, small. *Observe*: The essence of the character consists in the two barren antheræ, ESSENTIAL CHARACTER. *Calix*: seven-leaved, the two outer patulous. *Corolla*: irregular, reversed. *Stamina*: two, barren; capsule two-celled.—All the plants of this genus are little known in Europe.—The species are,

1. *Gratiola Officinalis*; *Officinal Gratiola*, *Hedge-hyssop*, or *Water-hyssop*. Leaves lanceolate-serrate; flowers peduncled; root perennial, creeping, thick, fleshy, with many slender fibres; stalks several, upright, a foot or more in height, smooth, jointed; flowers solitary, axillary, upright, on peduncles half an inch long, appearing in June and July, and continuing to August; calix usually seven-cleft; corolla shaped like that of the foxglove, but small, and of a pale yellowish colour, or pale purple, with red streaks, sometimes white; the throat is hairy. The whole plant is very bitter, and nearly resembles the foxglove, both in external appearance and virtues. Taken in moderate doses it purges briskly, and in larger quantities also vomits, and by thus operating carries off watery humours, and removes obstructing matter in a very powerful degree. The juice is a rough but excellent medicine in dropsies, and a strong decoction or infusion soon cures the jaundice; the root dried and powdered is frequently given successfully in the sciatica and rheumatic complaints, and in small doses will effectually destroy worms in the stomach and intestines, and by its purging qualities carries off that mucous and slimy matter in which they are there bred and harboured. The root of this plant very much resembles ipecacuanha in its nature and effects, and is equally to be depended on in purgings, the bloody flux, and agues. This, together with the fifth species, are easily propagated by parting the roots in autumn, when the stalks decay: the plants should have a moist soil and a shady situation, for in dry ground they often decay in summer, unless plentifully watered. Cattle will not touch this plant on account of its extreme bitterness; so that Haller assures us, there are meadows about Yverdon, in France, entirely useless

through the abundance of this plant.—Native of the South of Europe, generally found in moist pastures; common in many parts of Switzerland, Carniola, Austria, in the Palatinate, Silesia, France; about Turin, Padua, and other parts of Italy.

2. *Gratiola Monnieriæ*; *Thyme-leaved Gratiola*. Leaves oval-oblong; peduncles one-flowered; stalk creeping; root jointed, creeping, with small fibres; stalk herbaceous, inclined to be simple, round, leafy, smooth, somewhat erect, declining at bottom; peduncles longer than the leaves, filiform, solitary, axillary, one-flowered; corolla blue, inclined to bell-shape, a little flattened, five-cleft; the divisions nearly equal, the three upper ovate, spreading, the two lower converging, somewhat bent down. This small creeping plant sticks very close to the ground, and casts a few slender fibres from every joint as it creeps; the whole plant seldom exceeds seven or eight inches in length, but it generally grows in beds, and spreads thick upon the ground, throwing out a few simple side-branches, which make it very remarkable, and give it a pretty appearance when it flowers, which is from July to September.—Native of low moist soils in the East and West Indies, and South Sea Islands.

3. *Gratiola Repens*; *Creeping Gratiola*. Leaves ovate; stem creeping; calix five-leaved; style bifid.—Native of Jamaica.

4. *Gratiola Rotundifolia*; *Round-leaved Gratiola*. Leaves ovate, three-nerved; stems a finger high, quadrangular, smooth, creeping at the base; peduncles axillary, solitary, naked, alternate, one-flowered, longer than the leaves; stamina two, capsules compressed, roundish.—Native of sandy grounds in Malabar.

5. *Gratiola Hyssopoides*; *Hyssop-leaved Gratiola*. Leaves ovate-lanceolate, subserrate, much shorter than the internodes; stem filiform, upright, smooth, a foot high; peduncles axillary, alternate, solitary; one-flowered, several times longer than the leaves; calix very small; corolla much larger than the leaves, ringent.—Native of the rice grounds of Tranquebar, in the East Indies. See the first species.

6. *Gratiola Virginica*. Leaves lanceolate, obtuse, somewhat toothed; stem procumbent, varying much in size; peduncles axillary, one-flowered; the corolla is white, and the flowers are not followed by seeds in England.—It grows naturally in moist places in North America, where it rises more than a root high, but with us does not exceed eight inches: it is also a native of Malabar.

7. *Gratiola Peruviana*. Flowers subsessile. This plant has grown nine inches high, with a weak stalk in our climate; the flowers come out single on each side of the stalk, and are white, and much smaller than the common sort.—Mr. Miller received the seeds from Carthagenæ, in New Spain, where it was found in places where there had been standing waters, which were then dried up.

8. *Gratiola Lobelioides*. Stem almost naked, stipuled; leaves oblong, quite entire; panicle dichotomous; capsules subglobular; root numerous, in bundles, short, simple; stalk simple, upright, round, having an obscure broad furrow on each side, slightly streaked, smooth, with five stipuled joints, a foot high; panicle terminating, lax, thin, with peduncles mostly simple, alternate, remote, round, smooth, or sometimes with a few scattered hairs, slender, nearly equal, with bractes at the base, reddish green; flowers inferior; corolla tube streaked with a darker colour; border bell-shaped, the upper segment scarcely ascending, obcordate, flattish, shorter than the others, blue, the side ones straight, obliquely retuse at the ends, a little longer than the upper one, and of the same colour, the lower one spreading, obcordate, flattish,

adorned with a white heart-shaped spot, and a few blue dots, and twice as large as the others; throat naked, a little flattened; germen superior, ovate, smooth, with a small furrow on each side.—Native of rice-fields in Tranquebar.

9. *Gratiola Grandiflora*; *Great-flowered Gratiola*. Stems decumbent; leaves ovate-serrate; peduncles opposite; capsules subulate; stems angular, bifid, smooth; flowers large in proportion to the other parts; capsules long.—Native of Tranquebar, Madras, Siam, Malacca, where it is found in moist fat soils.

10. *Gratiola Veronicifolia*; *Veronica-leaved Gratiola*. Stem creeping; leaves ovate-lanceolate, sharply serrate; flowers terminating, opposite; stems angular, diffused, procumbent; flowers small, deep blue, bracted and peduncled; capsule five-cleft, linear.—Native of Tranquebar.

11. *Gratiola Oppositifolia*. Stem ascending; leaves lanceolate-serrate; peduncles opposite to the leaves; stems seldom upright, quadrangular, streaked.—Native of moist places and rice-grounds in Tranquebar.

12. *Gratiola Stricta*. Leaves ovate; spike long, terminating; stem suffruticose; flowers white, dotted with red, sessile, in a simple erect spike; calix none, except a triple bracte under the flower.—Native of Cochinchina.

Gravel.—There are different sorts of gravel: that upon Blackheath is said to be the best in England; it consists of smooth even pebbles, which, when mixed with a due quantity of loam, will bind very close, and preserve a beautiful appearance longer than any other sort. Some recommend a soil of iron-mould gravel, or gravel with a little binding loam amongst it, than which nothing they say binds better, when it is dry, but in wet weather it is very liable to stick to the shoes, and will never appear handsome. Sometimes loam is mixed with gravel that is over sandy or sharp, which should be well blended together, and suffered to lie in heaps, after which it will bind like a rock. There are many kinds of gravel which do not bind, and thereby cause a continual trouble of rolling, to little or no purpose; as for such, if the gravel be loose or sandy, you should take one load of strong loam to two or three of gravel, and so cast them well together, and turn this mixture over three or four times, that they may be properly blended together: when this is properly done, it will bind well, and not stick to the feet in wet weather. There are many different opinions about the choice of gravel; some are for having it as white as possible, and in order to make the walks more so, they roll them well with stone rollers, which are often hewn by the masons, that they may add a whiteness to the walks; but this renders it very troublesome to the eyes, by reflecting the rays of light so strongly, and on that account should be avoided. Such gravel as will lie smooth, and reflect the least, should be preferred. Some fall into the error of screening the gravel too fine; it should first be cast into a round heap, and will afterwards be the better for only having the great stones raked off. Others are apt to lay gravel walks too round, but this is also an error, which makes the walks appear narrow; one inch rise is enough in the crown for a walk of five feet wide, and the same proportion will be sufficient for every other width. For the depth of gravel-walks a foot thickness will be quite sufficient, but then there should always be a depth of rubbish laid under the gravel, especially if the ground be wet, for then too much care cannot be taken to fill the bottom of the walks with large stones, flints, brick, rubbish, chalk, or any other materials which can be best procured, which will drain off the moisture from the gravel, and prevent it from becoming poachy in wet weather; but as it may be difficult in some places to procure a sufficient quantity of

these materials to lay in the bottom of the walks, so that there may be a bed of heath or furze, whichever can be procured at the least expense, laid under the gravel to keep it dry; and if either of these be used green, they will lie a long time, as they will be covered from the air, and these will prevent the gravel from getting down into the clay, and will always keep the gravel dry; and where there is not this precaution in the first laying of the gravel upon clay, the water being detained by the clay, will cause the gravel to be poachy whenever there is much rain. In making of gravel-walks, there must be great regard had to the level of the ground, so as to lay the walks with easy descents towards the low parts of the ground, that the wet may be drained off easily; for if this be omitted, the water will remain upon the walks a considerable time after long rains, which will render them unfit for use, especially where the ground is naturally wet or strong; but where the ground is level, and there are no declivities to carry off the wet, it will be proper to have sink stones laid by the sides of the walks, at convenient distances, to let off the wet, and where the ground is naturally dry, the water will soon soak away: the drains of the sink-stones may be contrived so as to convey the water into sesh-pools, from which the accumulated water will gradually disappear in a short time; but in wet land there should be under-ground drains to convey the wet off, either into ponds, ditches, or the nearest place to receive it; for where this is not provided for, the walks will never be so handsome or useful. The month of March is the properest time for laying gravel; it is not prudent to perform it sooner, or to lay walks in any of the winter months: some persons indeed turn up gravel-walks in ridges in December, in order to kill the weeds; but this is very wrong, for besides that it deprives them of the benefit of them all the winter, it does not answer the end for which it is done, but rather the contrary; for though it does kill the weeds for the present, yet it adds a fertility to them, and ensures their future increase. If constantly rolling the ground after the rains and frost will not effectually kill the weeds and moss, turn the walks in March, and lay them down at the same time. In order to destroy worms, which spoil the beauty of both gravel and grass walks, some have recommended the watering them well with water in which walnut-tree leaves have been steeped, and made very bitter, especially those places most annoyed with them; and thus it is said, as soon as it reaches them, it will make them come out hastily, so that they may be gathered; but if in the first laying of the walks there is a good bed of lime-rubbish laid in the bottom, it is the most effectual method to keep out the worms, for they will never come near lime.

Greek Valerian. See *Polemonium*.

Greenhouse, and Conservatory.—These are buildings erected on the best principles for protecting and preserving such sorts of plants as are too tender to live in the open air. The greenhouse was originally a room in a garden, not far from the house, facing the south, and having large windows from top to bottom, built for the reception of oranges, myrtles, and a few other plants which were brought from temperate climates. This building had no flues, or contrivances of any sort for increasing the natural heat, but the air of the room was warmed merely by the sun. A great variety of curious exotic plants having been introduced into the English gardens, soon after the middle, and towards the end of the last century, flues were added to the greenhouse, and many other improvements and contrivances adopted into its structure. As to the length of the greenhouse, says Mr. Miller, it must be proportioned to the number of plants it is to contain, or the fancy of the owner; but the depth should never be

greater than the height in the clear, which in small or middling houses may be sixteen or eighteen feet, but in large ones from twenty to twenty-four feet is a good proportion; for if the green-house be long and too narrow, it will have a bad appearance from both within and without, nor will it contain so many plants, if proper room be allowed for passing in front and at the back of the stands on which the plants are placed; and, on the other hand, if the depth of the greenhouse be more than twenty-four feet, there must be more rows of plants placed to fill the house, than can with convenience be reached in watering and cleaning; nor are houses of too great depth so proper for keeping of plants as those of moderate size. The windows in front should extend from about one foot and a half above the pavement, to within the same distance of the ceiling, which will admit of a cornice round the building over the heads of the windows. As it is necessary to have these windows so long, it will be impossible to make them in proportion as to their breadth, for if the sashes be more than seven or seven feet and a half broad, they will be troublesome to move up and down, and their weight will cause them to decay very quickly. The piers between the windows should be as narrow as is consistent with their necessary strength to support the building, for which reason stone is preferable, or hard well-burnt bricks. If these piers be made of stone, they should be two feet and a half in diameter, worked as columns, cylindrical, whereby the rays of the sun will not be obstructed so much as if they were square; but if they be built of bricks, it will be proper to make them three feet in front, and they may be sloped off towards the inside to admit the sun. If a house for tools, &c. be erected at the back of the greenhouse, the back wall need not be more than two bricks and a half in thickness; but if not, it must be three bricks or three bricks and a half thick to keep out the frost. The floors of the greenhouse may be laid with Bremen squares, Purbeck stone, or broad tiles, and must be raised two feet above the ground, where the soil is dry; but if the situation be moist and springy, the floor should be raised at least three feet above the surface, and if the whole be arched with low brick arches under the floor, it will tend to prevent the damp from rising in winter. These damp are often very hurtful to the plants, especially in great thaws, when the air is often too cold to be admitted into the house to remove the damp. Under the floor, about one foot from the front, a flue one foot in width, and two feet in depth, may be carried the whole length of the house, which may be returned against the back wall, and carried up in proper funnels adjoining to the hot-house, three times over each other, by which the smoke may pass off. The fire-place may be at one end of the house, and the door at which the fuel is put in, as well as the ashes-grate, may be contrived to open into the tool-house, so that it may be quite hid from sight, and kept dry. The fuel also may be laid in the same shed, and thus will always be ready for use. The wall on the back part of the house should be either laid over with stucco, or plastered with mortar, and white-washed, to keep out the frost, which will penetrate through the walls, especially when it is attended with a strong wind. To prevent frost from penetrating through the roof, reeds, heath, or furze, should be laid between the ceiling and the tiles; and care taken in framing the joints, that the weight may not lie upon the ceiling; for they should be laid a foot thick at least, as smooth as possible, and fastened down well with laths, and then covered over with a coat of lime and hair; which will keep out the air, and also prevent mice and other vermin from entering, which, if left uncovered, they would certainly do. In the greenhouse

there should be tressels, which may be moved in and out, upon which rows of planks should be fixed, so as to place the pots or tubs of plants in regular rows one above another, whereby the heads of the plants may be so situated as not to interfere with each other. The lowest row of plants, or forwardest towards the windows, should be placed about four feet from them, that there may be a convenient breadth left next the glasses to walk in front; and the rows of plants should rise gradually from the first, in such a manner that the heads of the second row should be entirely advanced above the first, the stems only being hid; and at the back of the house there should be allowed a space of at least five feet, for the conveniency of watering the plants, and to admit a current of air round them, that the damps arising from their perspiration may be the more readily dissipated; which, by being pent in too closely, often occasions a mouldiness upon the tender shoots and leaves, and when the house is closely shut up, this rancid and stagnating vapour is often very destructive, and on this account the plants should never be crowded together, nor should succulent plants be placed among them. The plants are put into the greenhouse in October, or as soon as the morning and evening frosts come on. In this situation they remain till the end of May or the middle of June, according to the season; when they are removed to the place where they are to stand through the summer. Much of their growth and success depends upon the choice of a sheltered and convenient situation for them at this season; it must not be exposed to the meridian sun, nor to the west or north winds, both which are extremely hurtful to them when first exposed, and again in the autumn. Here they must be refreshed with waterings at least three times a week. Before the plants are removed out of the greenhouse, it is necessary to shift at least all the small plants; that is, to take them out of their pots, to cut off part of their roots round the ball of earth, and to put them again into the same pot, if the plant be in an unhealthy state; or, if healthy, into one a size larger, shortening the irregular side-branches as they may require, and tying them up neatly. The mould into which the plants are to be shifted, is of considerable importance; the best is to be obtained from commons where sheep and cattle pasture, particularly in low places, where the finest grass grows in the deepest soil. A foot of the top soil with the turf may be taken off; and if it be a sandy or hazel loam, it will do alone; but if it be a strong loam, some sand and black peaty or moorish soil should be added. Such soils, laid in a heap for at least six of the winter months, and frequently turned over, will suit most greenhouse plants. Aloes, mesembryanthemums, ixias, and such liliaceous plants in general as are inhabitants of exotic houses and glass-cases, require a soil which is a degree lighter, and which will not retain the water, but let it pass readily; and a little coal-ashes at the bottom of each pot may be very useful for this purpose. The great number of ericas or heaths, and other beautiful plants from the Cape of Good Hope, from America, and Botany Bay, delight and flourish in that sort of earth which comes nearest to their native soil. Thus the heaths like a black peat, or moorish soil, and the others that which is made a degree stronger with loam.—*Conservatory.* Greenhouse and Conservatory have been generally considered as synonymous terms for a house of a certain construction, destined to the preservation of exotic plants throughout the winter. Their essential difference is this: In the greenhouse, the trees and plants are either in tubs or pots, and are placed on stands or stages through the winter, till they are removed into some sheltered situation abroad for the summer. In the conser-

vatory, the ground plan is laid out in beds and borders, made up of the best compositions of soils that can be procured, three or four feet in depth. In these the trees and plants, taken out of their tubs or pots, are regularly planted in the same manner as hardy plants in the open air. Instead of taking out the plants in summer, as in the greenhouse, the whole of the glass roof is taken off, and the plants are thus exposed to the open air; and at the approach of autumn frosts the lights are again put on, and remain so till the May or June following. It is evident that the building here called a conservatory may also be used as a greenhouse, at the discretion of the owner, by introducing stages instead of beds, and in that case the glass roof may be fixed. In Mr. Miller's plan, the greenhouse or conservatory is placed exactly fronting the south, one of the wings or stoves facing the south-east, and the other the south-west; so that from the time of the sun's first appearance upon any part of the building, until it goes off at night, it is constantly reflected from one part to the other, and the cold winds are also kept off from the front of the centre building. In the area many of the more tender exotic plants may be placed in the summer season; and in the spring, before the plants can be set out, the beds and borders of this area may be full of anemones, ranunculuses, early tulips, &c. which will be past flowering, and the roots fit to take out of the ground, by the time the plants are taken out. In the centre of this area, may be a small basin of water, which will be very convenient for watering the plants, not only on account of its nearness, but because the water will be softened and warmed by the reflection from the glasses. The wing facing the south-east should always be preferred for the warmest, or bark-stove, because the sun, at its first appearance in the morning, shines directly upon the glasses, and, warming the air of the house, gives new life to the plants, after the long nights of the winter season. In these buildings, if there are not sheds running behind them their whole length, the walls should not be less than three bricks thick, and if they are even more it will be better; because where the walls are thin and exposed to the open air, the cold will penetrate, and when the fires are made the heat will come out through the walls, so that it will require a large quantity of fuel to maintain a proper temperature of warmth in the house; and in general the closer and better these houses are built, the less fuel will be required to warm them; so that the first expence in building them properly and substantially will be the cheapest, when the after expence of fires is taken into consideration. Besides these buildings, it will be proper to have deep hot-bed frames, such as are commonly used to raise large annuals in the spring, into which may be set pots of such plants as come from Carolina, Virginia, &c. whilst the plants are too small to bear the open air; as also many other sorts from Spain, and other southern countries of Europe, which require only to be screened from the violence of frosts, and should have as much free air as possible in mild weather. This cannot be better effected than by one of these frames, where the glasses may be taken off every day when the weather will permit, and put on every night; and in hard frosts the glasses may be covered with mats, straw, pease-haulm, or similar materials, to preserve the roots of the plants from the frost. If these pits be sunk a foot or more below the surface of the ground, it will be better, provided the ground be dry. The sides of the frame should be built with brick, and a curb of wood laid round on the top of the wall, into which the gutters whereon the glasses slide may be laid. The back wall may be four feet high, and two bricks and a half thick; the front, one a foot and a half; the width of the inside of the

frame, about six feet; and the length in proportion to the number of plants to be contained in it.

Greenweed, or Greenwood. See *Genista*.

Grewia; a genus (according to Linneus) of the class Gynandria, order Polyandria; removed by Schreber into the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets lanceolate, upright, leathery, coloured within, spreading, deciduous. *Corolla*: petals five, the same form with the calix, often smaller, emarginate at the base; nectary, a scale inserted into each petal at the base, thickish, bent in, inclined to a rim surrounding the style. *Stamina*: filamenta very numerous, the length of the petals, bristle-shaped, inserted into the base of the germen; antheræ roundish. *Pistil*: germen pedicelled, roundish, sitting on a columnar upright receptacle, surrounded by a five-cornered rim; style filiform, the length of the stamina; stigma obtuse, four-cleft. *Pericarp*: berry four-lobed, four-celled. *Seeds*: solitary, globular, one-celled. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: five, with a nectareous scale at the base of each; berry four-celled.—The species are,

1. *Grewia Occidentalis*; *Elm-leaved Grewia*. Leaves subovate; flowers solitary. This plant will grow to the height of ten or twelve feet, and has a stem and branches very like those of the small-leaved elm, the bark being smooth, and of the same colour as that of elm when young; the leaves are also very like those of the elm, and fall off in winter; the flowers are produced singly along the young branches from the axils, and are of a bright purple colour; they appear towards the end of July, and continue through August to the beginning of September, but are never succeeded by fruit in this country. The common *grewia* may be propagated by cuttings or layers: the cuttings should be taken off and planted in April, before the buds swell, for they do not succeed well after; these cuttings should be planted in small pots filled with loamy earth, and the pots should be plunged into a moderate hot-bed of tanner's bark, where, if they are duly watered, and in the heat of the day sheltered from the sun, they will take good root in about two months, and may then be gradually inured to bear the open air, into which they should be removed in June, and placed in a sheltered situation, where they may remain till autumn, when they must be removed into the greenhouse. The best time to lay down the layers of this plant, is in the spring, before the buds come out, and these will be rooted by the same time the following year, when they may be cut off from the old plants, and planted each into a separate pot filled with a soft loamy soil. The best time to remove or transplant this plant is, either in the spring just before the buds begin to swell, or in autumn when the leaves begin to drop; for in summer, when the plants are in full leaf, it will be very improper to disturb them. In winter they should be placed in the greenhouse, for they are too tender to live abroad in England; but they should have as much free air as possible in mild weather, for they only require to be protected from frost, and after their leaves are fallen they will require very moderate watering; but in summer they should be watered three or four times a week in dry weather, and placed in a sheltered situation, with other hardy greenhouse plants, where they will add to the variety. The other species of this genus will not live through an English winter, unless they are placed in a warm stove; nor do those plants thrive well which are placed on shelves in the dry-stove; therefore the only method to ensure their succeeding is, to place them in the bark-bed in the tan-stove. In summer these plants require a good share of free air to be admitted to them, and

should have water three or four times a week in warm weather; but they must be kept warmer in winter, and sparingly watered.

2. *Grewia Populifolia*; *Poplar-leaved Grewia*. Leaves orbiculate; peduncles solitary, one-flowered. This is a branching shrub; the branches are slender, smooth, and ash-coloured. Bractes in pairs, on the middle of the peduncle, deciduous; calicine leaflets linear, obtuse, villose, smooth within, coloured; petals linear, shorter than the calix. It is allied to the first species, but of a looser habit.—For its propagation and culture see the first species.

3. *Grewia Orientalis*; *Oriental Grewia*. Leaves sublan- ceolate; flowers solitary. This is a middling sized tree. Peduncles from the axils tomentose, trifid, three-flowered. Berry subglobular, depressed, becoming obtusely four-cornered, and drying, succulent; the skin when fresh saffron-coloured, villose, flesh pulpy, fugacious; stones hard like grape-stones, having a deep furrow on the back, two-celled. It flowers in July and August.—Native of the East Indies. For its propagation and culture see the first species.

4. *Grewia Lævigata*. Leaves elliptic, acuminate, smooth on both sides, quite entire at the base; peduncles three-flowered; branches with a purple bark dotted with white; pedicels almost the length of the petioles.—Native of the East Indies. See the first species.

5. *Grewia Glandulosa*. Leaves ovate, lanceolate, acuminate, smooth on both sides, glandular at the base; flowers solitary, subsessile; branches somewhat rugged; petiole short; flowers axillary on very short peduncles.—Native of the Isle of France. See the first species.

6. *Grewia Hirsuta*. Leaves lanceolate, ovate, soft; calices very hairy; peduncles three-flowered; branches soft with hairs, especially at top; flowers subsessile, with a three-leaved lanceolate involucre; petals very short, oblong, ciliate. Found by Koenig on the tops of mountains in the East Indies.—For its propagation and culture see the first species.

7. *Grewia Excelsa*. Leaves oblong, beneath tomentose, hoary; peduncles axillary, often solitary, three-flowered; pedicels angular.—See the first species.

8. *Grewia Asiatica*; *Asiatic Grewia*. Leaves cordate. A tree with the branches scarcely tomentose; stipules lanceolate; petioles round, tomentose, one-fifth the length of the leaves; peduncles axillary, usually in fours, trifid, three-flowered, half the length of its leaves; petals not bigger than the calix; berries small, red, acid.—Native of Suratte in the East Indies. For its propagation and culture see the first species.

9. *Grewia Filiaefolia*. Leaves cordate, roundish, smooth on both sides; peduncles shorter than the petiole; branches smooth, with brown bark, very minutely dotted with ash-colour, the younger ones subvillose; petioles powdered at the tip, scarcely thickened; stipules half-cordate, acuminate, shorter than the petiole; peduncles axillary, two or three together, three-flowered; involucre three-leaved; leaflets lanceolate, obtuse, concave, the length of the pedicels; fruit two-grained.—Native of the East Indies. For the propagation and culture see the first species.

10. *Grewia Malococca*; *South Sea Grewia*. Leaves cordate, ovate, oblong, crenate, scabrous; pedicels axillary, three-flowered; fruit tetracoccous. The difference by which it is distinguished from other species is difficult to make out. It is distinct by having no scales to the petals; the germen sessile, and the stones or nuts not two-celled. The berry is obtusely four-cornered, depressed, scabrous on all sides, with minute bristles. Seeds solitary, and four in the whole berry, obovate, remarkably tapering downwards, somewhat livid.—Native of

the island of Tongatabu and Huaheine in the South Seas.—For its propagation and cultivation see the first species.

11. *Grewia Velutina*. Leaves oval, very soft on both sides, hoary underneath; peduncles axillary, about three together, three-flowered; stem shrubby. All parts of the plant very soft with nap. Petioles very short; stipules bristle-shaped, deciduous; peduncles the length of the petioles. Flowers smaller than those of the eighth species.—Native of the East Indies. For the propagation and culture see the first species.

12. *Grewia Salvifolia*; *Sage-leaved Grewia*. Leaves oblong, quite entire; flowers axillary, several pedicelled; petals bowed back, linear. This is a shrub. Peduncles three or more, tomentose, short; flowers upright; calix five toothed, tomentose; petals tomentose, upright, yellow, bifid at the tip.—Native of the East Indies. See the first species.

13. *Grewia Microcos*. Leaves ovate, oblong; flowers panicked. This is a tree. The flowers are terminating, and the calices tomentose.—Native of the East Indies. See the first species.

Grias; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth, one-leafed, cup-shaped; mouth four-cleft, finally lacerated. *Corolla*: petals four, roundish, concave, coriaceous. *Stamina*: Filamenta numerous, setaceous, longer than the corolla, inserted into the receptacle; antheræ roundish. *Pistil*: germen somewhat depressed, immersed in the calix; style none; stigma thickish, four-cornered, hollowed out crosswise. *Pericarp*: drupe large, one-celled, acuminate at the base and tip. *Seeds*: nucleous scored with eight furrows. **ESSENTIAL CHARACTER.** *Corolla*: four-petalled. *Calix*: four-cleft; stigma sessile, cross-shaped; drupe with an eight-furrowed nucleus.—The only known species is,

1. *Grias Cauliflora*; *Anchovy Pear*. Branches at the top simple, short, or none; leaves on short petioles, pendulous, two or three feet long, wedge-shaped at the base, oblong, attenuated, entire, marked with nerves and veins, wrinkled, smooth; flowers from the stem, on very short, scaly, many-flowered peduncles; pedicels short crowded, one-flowered; corollas large, whitish. This tree frequently grows to the height of fifty feet. The uprightness of the growth, and the largeness of the leaves, give this tree a very elegant appearance. The fruit is pickled in the West Indies, and eaten in the same manner with the East Indian Mango, which it exactly resembles in taste. It is about the size of an alligator's egg, and much like it in shape, only a little more acute at one end, and of a brown russet colour. This beautiful tree is common in many parts of Jamaica, and grows generally, in low moist bottoms, or shallow waters.—Put the stones into the ground soon after the fruit is gathered, and keep the plants constantly in the bark-bed in the stove. In the West Indies the seeds grow very readily, wherever they meet with a sufficient quantity of moisture, and propagate so thick, that the trees are always found formed into thickets, or large clusters.

Grielum; a genus of the class Decandria, order Pentagynia.—**GENERIC CHARACTER.** *Calix*: perianth, one-leafed, spreading, deeply five-cleft, flat at the base, sharp, equal, permanent. *Corolla*: petals five, spreading, large, obovate, sessile, tapering at the base; nectaries oblong; glands placed round the germen, and united so as to form a crown. *Stamina*: filamenta ten, filiform, somewhat rigid, equal, permanent, the length of the calix; antheræ ovate, oblong, upright. *Pistil*: germen five, distinct, awl-shaped, upright, shorter than the stamina; styles none; stigmas wanted. *Pericarp*: five, oblong, acuminate, hard; capsule formed

from the calix, hardened, round, flattened, five or ten celled. *Seed*: solitary, oblong. *Observe*. It is not certain whether there be a difference of sex, or a withering of the pistil in some individuals. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Petals*: five. *Filamenta*: permanent. *Pericarp*: five, with one seed in each.—The only known species is,

1. *Grielum Tenuifolium*. The petals are blue, with livid yellow claws. Capsule inferior, with the calix closely adhering, and serving as a bark to it at bottom, flattish at top, and surrounded with a ring of hard bony tubercles, within which it is crowned with the permanent filamenta and styles: it has ten cells, but no valves: to each style there are two cells, but all of them are placed in a ring, regularly round the axis of the fruit, and deeply immersed in the substance of the calix. There is no receptacle, but the seeds are fixed to the tip of the cells, only one in each; the form is elliptic, beaked at top, plano-convex, or flattened lens-shaped, of a reddish chesnut colour.—Native of the Cape of Good Hope.

Grimmea; a genus of Mosses, comprehending some Linnean species of *Bryum*.

Grislea; a genus of the class Octandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth, one-leafed, awl-shaped, inclined to bell-shape, upright, four-toothed, coloured, permanent. *Corolla*: petals four, ovate, from the incisures of the calix extremely minute. *Stamina*: filamenta eight, awl-shaped, upright, long, ascending; antheræ simple, upright, roundish. *Pistil*: germen superior, globular, pedicelled; style filiform, the length of the stamina; stigma simple. *Pericarp*: capsule globular, shorter than the calix, one-celled. *Seeds*: very many, roundish, very small; receptacle large. *Observe*: Sometimes one-third part is added to the parts of the flower. **ESSENTIAL CHARACTER.** *Calix*: four-cleft. *Petals*: four from the incisures of the calix. *Filamenta*: very long, ascending. *Capsule*: globular, superior, one-celled, containing many seeds.—The species,

1. *Grislea Secunda*. Leaves ovate, lanceolate, smooth, on petioles; raceme terminating; flowers all facing one way. This is a tree with round branches. Calices green, turbinate; petals scarcely conspicuous; antheræ fulvous.—Native of South America.

2. *Grislea Tomentosa*. Leaves half-lanceolate, with a cordate base, whitish beneath, sessile; racemes axillary, short; stem and principal branches erect, smaller, ascending; bark rust-coloured; calix red, six-toothed, equal, permanent; petals six, small, lanceolate. This is a beautiful flowering shrub, a native of the hills and valleys through the northern provinces of the Carnatic in the East Indies. The bright red calix, retaining its colour till the seeds be ripe, gives this plant a very showy appearance.—Linneus says it is also a native of the West Indies.

Gromwell. See *Lithospermum*.

Gronovia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, five-cleft beyond the middle, bell-shaped, coloured, permanent; divisions semi-lanceolate, upright. *Corolla*: petals five, extremely minute, roundish from the clefts of the calix. *Stamina*: filamenta five; capillary, length of the corolla, inserted into the calix, alternate with the petals; antheræ erect, twin. *Pistil*: germen inferior; style filiform, longer than the stamina; stigma obtuse. *Pericarp*: berry dry, roundish, coloured, one-celled. *Seed*: single, roundish, large. **ESSENTIAL CHARACTER.** *Petals* five, together with the stamina, inserted into the bell-shaped corolla. Berry dry, inferior, containing one seed.—The only known species is,

1. *Gronovia Scandens*: *Climbing Gronovia*. This is an annual plant, which sends forth many trailing branches like those of the cucumber, closely set with broad leaves, in shape like vine-leaves; those on the stalk are covered with small spines, or rather hooked hairs, which sting like the nettle: the branches have many tendrils, by which they fasten themselves to other plants, and thus will rise to the height of six or eight feet. The flowers are small, axillary, and in bunches, of a greenish yellow colour, and make no great appearance. It has a strong smell.—Native of Vera Cruz. This being a very tender plant, must be raised on a hot-bed early in the spring, and afterwards placed in the bark-stove, and treated in the same way as the *Momordica*. If treated in this manner it will produce ripe seeds.

Ground Ash. See *Ægopodium*.

Ground Ivy. See *Glechoma*.

Ground Rattan. See *Rhapis Flabelliformis*.

Groundsel. See *Senecio*.

Groundsel-tree. See *Baccharis*.

Guaiacum; a genus of the class Decandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate, oblong, concave, obtuse, spreading, deciduous; the two outer ones a little smaller. *Corolla*: petals five, roundish, obovate, obtuse, concave, spreading, longer than the calix, ending in short claws, inserted into the receptacle. *Stamina*: filamenta subulate, broader at the base, upright, shorter than the corolla, inserted into the receptacle; antheræ oblong, finally recurved. *Pistil*: germen broader above, angular, pedicelled; style short, subulate; stigma simple, acute. *Pericarp*: capsules two to five, on very short pedicels, compressed, membranaceous, covered with a pulpy rind, gibbous on the outside, united on the inside, separating when ripe, gaping. *Seeds*: solitary, bony, oblong. **ESSENTIAL CHARACTER.** *Calix*: five-cleft, unequal; petals five, inserted into the receptacle; capsule angular, five-celled.—The species are,

1. *Guaiacum Officinale*; *Officinal Guaiacum*, or *Lignum Vitæ*. Leaves in two pairs, obtuse. This grows to be a very large tree, covered with a hard, brittle, brownish bark, not very thick. The wood is firm, solid, and ponderous, appearing very resinous, of a blackish yellow within, and of a hot aromatic taste. The smaller branches have an ash-coloured bark. Petals ovate, entire; leaflets two pairs, elliptic, sessile, entire, veined, shining. Browne describes this tree as an evergreen of a dark gloomy cast, continuing its verdure in the driest seasons, and at times throwing out a great number of blue flowers, which are succeeded by compressed berries of a roundish form. The tree takes many years to arrive at its full growth. The roots run far into the ground perpendicularly, contrary to the usual growth of timber-trees in the West Indies, which generally shoot the largest prongs of their roots in an horizontal direction, and are commonly observed to run very near the surface. The bark is thick and smooth; the wood of a dark olive colour, and cross-grained, the strata running obliquely into one another in the form of an X. As timber it answers where strength and duration are required, and its weight no impediment. It takes a fine polish, and answers well in the turner's lathe; but is now chiefly used for the sheaves of ships' blocks. The tree rises to the height of forty feet, and measures from fifteen to eighteen inches in diameter. It is certainly one of the most valuable in the West Indies; since the body, the bark, gum, fruit, leaves, and blossom, are all applicable to some useful purpose. The gum is obtained by jagging the body of the tree in May. It exudes copiously from the wounds, though gradually; and when a quantity is found accumulated, hardened by

exposure to the air and sun, it is gathered and packed in small kegs. This gum is sometimes suspected to have been sophisticated by the negroes, with the gum of the manchineal-tree, to which it bears some similitude at the first appearance; but it is easily distinguished by dissolving a little in spirits: the true gum imparts a whitish tinge; but the manchineal gives a greenish cast: and this is still further distinguishable by pouring a little of the same tincture into water, which takes from the guaiacum almost immediately the complexion of milk. The fruit is purgative; and for medicinal use, far excels the bark. From the flowers is prepared also a laxative syrup, resembling syrup of violets. The fresh bark opens the body, and is deemed a sweetener of the blood; but the pulp of the berries purges and vomits very violently. The resinous parts of the tree are of a warm, active nature, and found by long experience to attenuate and dissolve the blood; they are esteemed specifics in old venereal taints, chronical rheumatisms, and other disorders arising from the sizyness of the juices, and generally administered in decoctions, the resin sometimes in boluses, ordered for a continuance; but great care must be taken to moderate or temper the native acrimony of these medicines in the beginning of a course, and to prepare the body for the use of them; the neglect of which has been frequently the cause of very dismal consequences in hot climates, and may probably have the like effects sometimes in colder regions. There is a tincture made with the gum of this tree that has been sometimes administered with success, as well as the powder itself, in obstinate intermittent and remittent fevers; in which cases they commonly procure a few stools, as well as promote a general discharge by the skin. The foliage of this tree is of a very detersive nature, and frequently used to scour and whiten the floors in most houses about Kingston: the infusion of them is also used to wash painted linens, and other stained garments; which it is said to do very effectually, without changing the lustre of their dyes. The wood and resin only are now used in Europe. Since the introduction of mercury it is seldom prescribed in the lues venerea; if, when occasionally employed in *syphilis*, it is rather with a view to correct other *vitia* in the habit. Dr. Cullen looks upon it as analogous to the balsams and turpentine, and as having a considerable power in stimulating the extreme vessels; and thus accounts for its efficacy in chronic rheumatism; and from its passing off by the pores of the skin, he considers it as a probable remedy in some cutaneous disorders. In the London Dispensatory there is a tincture of Gum Guaiacum (*Pulvis Aloeticus cum Guaico*), and the wood is an ingredient in *Decoctum sarsaparillæ compos*. The Edinburgh college have directed an elixir to be prepared with rectified spirit, or with the vinous spirit of sal ammoniac: some object to the spiritous tincture, and Dr. Cullen prefers the diffusion of the gum in water. It is a native of the West Indies. In Jamaica it is abundant on the south side, but is seldom found in any other part of the island.—This and the second species can only be propagated by seeds procured fresh from the countries where they naturally grow. As soon as they arrive they should be sown in pots, filled with light earth, and plunged into a good hot-bed, and, if the seeds be good, they will appear in six weeks or two months; in six weeks more they will be strong enough for transplanting; then they should be carefully taken out of the seed pots, so as to preserve their roots as entire as possible, and each planted in separate small pots filled with light earth, and plunged into a new hot-bed of tanner's bark, where they must be shaded from the sun till they have taken fresh root; then they must be treated in the same manner as other tender exotic plants

from warm countries, admitting a large share of free air to them when the weather is warm; at which time it must be given with great caution, for too much wet will infallibly destroy them: while the plants are young, they may be kept during the summer season in a hot-bed of tanner's bark under a frame; but in the autumn they must be removed into the bark-stove, and plunged into the hot-bed of tan, where they should constantly remain, and must be treated in the same manner as other tender plants, being careful not to give them too much water in the winter, when it is very prejudicial to them; and in summer they should have a large share of free air admitted to them every day. With this treatment the plants will thrive very well; but being plants of slow growth in their own country, cannot be expected to make great progress in Europe. In their native country they grow very readily from seed; and seem fond of a dry soil with a hot exposure.

2. *Guaiacum Sanctum*. Leaflets many pairs, obtuse. It has many leaflets placed along the midrib by pairs; they are rounded and obtuse at their ends, but narrow at their base, of the same consistence with those of the first sort, but of a darker green colour. The flowers are produced in loose bunches towards the ends of the branches, are of a fine blue colour, and the petals are fringed on their edges. This is called *Bastard Lignum Vitæ* in some of the West India Islands.—For its propagation and culture see the first species.

3. *Guaiacum Afrum*. Leaflets many pairs, acute; branches rigid; leaves alternate, with eight pairs of leaflets; stipules pressed close to the branches, subulate, very small.—Native of Mossel bay, near the Cape of Good Hope. This will live in a good greenhouse all the winter, but in summer it must be placed abroad with other greenhouse plants. It is of a slow growth, and is with difficulty propagated by layers.

4. *Guaiacum Dubium*. Leaves conjugate, oblong, lanceolate, obtuse.—Native of the island of Tongatabu in the South Seas.

Guarea; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, four-parted, flattish, short. *Corolla*: petals four, spreading, lanceolate, obtuse; nectary tubular, cylindric, quite entire, length of the corolla, contracted at the throat. *Stamina*: filamenta none; antheræ eight, growing to the inner edge of the nectary, ovate. *Pistil*: germen roundish, on a very short pedicel; style subulate, thick, length of the nectary; stigma four-cornered, depressed. *Pericarp*: capsule roundish, large, subsessile, four-grooved, four-celled, four-valved. *Seeds*: solitary, oblong, with a scarlet aril. *Observe*: It should be distinguished from *Trichilia*, to which it is nearly allied. ESSENTIAL CHARACTER. *Calix*: four-cleft. *Petals*: four. *Nectary*: cylindric, bearing the antheræ at its mouth. *Capsule*: four-celled, four-valved. *Seeds*: solitary.—The only known species is,

1. *Guarea Trichilioides*; *Ash-leaved Guarea*. This is a middling-sized tree, with a smooth trunk. Racemes a foot long, axillary, subdivided, loose; the branches many-flowered; the peduncles very short; calix four-cornered, minute; segments blunt, spreading; leaves pinnate, without an odd leaflet. All parts of this plant, especially the bark, smell strong of musk, and may be used instead of that perfume, for many purposes. The wood is full of a bitter resinous substance, which renders it unfit for rum hogsheads; being observed to communicate both its smell and taste to all spiritous liquors: but it is often cut for staves and heading, when there is a scarcity of other lumber. The powder of the bark is said to be a good emetic; and is sometimes used among the negroes for that purpose.—Native of South America and the West

India Islands, in woods and by river sides, where it flowers in January and February. The English call it *musk-wood* and *alligator-wood*; the French *bois rouge*.

Guettarda; a genus of the class Monœcia, order Heptandria.—GENERIC CHARACTER. *Calix*: perianth one-leafed, cylindric, very short, quite entire, the outer edge more prominent, deciduous. *Corolla*: one-petalled, funnel-shaped; tube cylindric, long; border six to nine cleft, with rounded lobes shorter than the tube. *Male Flowers*. *Stamina*: filamenta four to six or seven in the throat of the corolla; antheræ linear. *Pistil*: style filiform. *Female Flowers*. in the same plant. *Pistil*: germen roundish, inferior; style filiform, longer than the stamina; stigma subovate. *Pericarp*: drupe dry, roundish, depressed, torose, according to Jussieu with a sinous nut, six-celled, and containing six seeds. *Seed*: nut lobed, celled, perforated in the periphery for cells; kernels solitary, four to six, roundish, bent at right angles. *Observe*: Number of parts and cells various. Some flowers have six, others four stamina. ESSENTIAL CHARACTER. *Calix*: cylindric. *Corolla*: six or seven cleft, funnel-shaped. *Pistil*: one. *Drupe*: dry.—The species are,

1. *Guettarda Speciosa*. Leaves subcordate, ovate, obtuse, with a point, silky underneath; flowers with six or seven stamina. This tree seldom rises above eight or ten feet in height, or exceeds three or four inches in diameter. The bark is smooth, and the disposition of the flowers very remarkable, as well as the texture and form of the leaves.—Native of Jamaica, Java, and the Society Islands in the South Seas.

2. *Guettarda Rugosa*. Leaves subcordate, ovate, acute, tomentose beneath, scabrous above; flowers with six stamina; branches round, opposite, scarred, smooth below, villose above; tube of the corolla an inch and an half long, soft, and somewhat silky; fruit the size of a pea, ash-coloured, with villose hairs.—Native of the East Indies.

3. *Guettarda Elliptica*. Leaves elliptic, pubescent; flowers with four stamina.—Native of Jamaica.

4. *Guettarda Membranacea*. Leaves ovate, acuminate, membranaceous, subhispidly scabrous; flowers with four stamina.—Native of St. Domingo.

Guilandina; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed; tube short, turbinate, permanent, with an oblique mouth; border five-parted, nearly equal, spreading, deciduous; divisions oblong, broader on the outside and rounded; the two upper ones a little shorter, the lowest a little longer. *Corolla*: petals five, inserted into the neck of the calix; the uppermost roundish, concave, ascending, a little shorter; the rest oblong, broader in front, rounded at the tip, reflex, spreading, longer than the calix, and the two lowest a little longer than the middle ones. *Stamina*: filamenta subulate, thicker at the base, and villose, decumbent, inserted into the neck of the calix, shorter than the corolla, unequal; the lower ones gradually longer; antheræ oblong, affixed to the back. *Pistil*: germen oblong; style filiform, length of the stamina; stigma simple. *Pericarp*: legume rhomboidal, the upper suture convex, from swelling compressed, one-celled, with transverse partitions. *Seeds*: bony, globular-compressed, solitary between the partitions. ESSENTIAL CHARACTER. *Calix*: one-leafed, salver-shaped. *Petals*: inserted into the neck of the calix, nearly equal. *Seed-vessel*: a legume.—The species are,

1. *Guilandina Bonduc*; *Yellow Bonduc*, or *Nicker Tree*. Prickly: pinnae ovate, with solitary prickles on the leaflets; leaves nearly a foot and a half long, composed of six or seven pairs of pinnae, each of which has as many parts of leaflets, which are ovate and entire; the principal midrib of the leaf

is armed with short, crooked, single thorns, placed irregularly; the stalks are also armed with thorns, which are larger. At first they grow erect, but afterwards twine about the neighbouring trees and shrubs. The flowers are in long axillary spikes. Legume broad, thick, three inches long, and two broad, closely armed with slender spines, opening with two valves, each enclosing two hard seeds about the size of children's marbles, of a yellowish colour.—This, together with the second, third, and fourth species, will not live through the winter in England, unless placed in a warm stove, and the pots plunged into the tan-bed. They are propagated by seeds; but those of the two first sorts are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they will remain years in the ground without vegetating: when the plants come up, they will be fit to transplant in a short time; then they should be each transplanted into a small pot, filled with light fresh earth, and plunged into a moderate hot-bed of tanner's bark, shading them till they have taken fresh root. They must afterwards be treated in the same manner as other tender exotic plants, giving them a large share of air in warm weather, and but little water; and when the plants have advanced to be too tall to remain in the frames, they must be removed into the bark-stove, and plunged into the hot-bed, where they will make great progress, provided they have not too much water, especially during the winter season, for these plants are very impatient of moisture in cold weather.

2. *Guilandina Bonducella*; *Gray Bonduc*, or *Nicker Tree*. Prickly; pinnae oblong-ovate, with double prickles on the leaflets. This differs from the first species in having much smaller leaves, set closer together; and below each pair of leaflets are two short, stiff, crooked spines, which are opposite; the flowers are of a deeper yellow, and the seeds are ash-coloured. These seeds are said to be useful in intermittents when powdered; and both these, and those of the preceding species, are taken by the negroes in venereal cases. The whole plant is weakly, and spreads a great way about the roots, or rises among the neighbouring bushes wherever it finds a due support. The stalk and branches are very full of thorns that arch backwards. The seeds are gray, and commonly used instead of marbles by boys in the sugar-colonies. In Egypt, the nuts of both these sorts are used by the women strung in necklaces, and hung about their children by way of amulets, to guard them from sorcery. They are often cast ashore on the north-west coasts of Ireland and Scotland, and are called by the inhabitants of the latter Molucca Beans. This tree make a good fence.—It is a native of both Indies, China, and New Zealand.

3. *Guilandina Nuga*. Stem unarmed; the primary petiole of the leaves with double prickles underneath; branches thorny; leaves thick, solid, smooth, opposite; flowers yellow; legumes smooth.—Native of Amboina and Malabar, in swamps by the sides of rivers.

4. *Guilandina Moringa*; *Smooth Bonduc*. Unarmed; leaves subbipinnate; lower leaflets ternate. This tree has a thick root of a softer substance than usual. The trunk is of a middling size, from twelve to twenty feet in height, smooth, with an ash-coloured bark; branches rather erect; flowers racemes, which are long, axillary, round, pubescent, subdivided, many-flowered; the subdivisions branched, directed one way, bent down; under these are minute deciduous scales. The root when young is scraped, and used by the inhabitants of Egypt as horse-radish is in Europe, having much the same sharp taste; as have also the seeds.—Native of the East Indies; cultivated in Jamaica and Egypt. This

species requires the same treatment as those before mentioned, but the seeds will grow without being steeped in water, and the plants are with difficulty shifted from one pot to another, for their roots are large, fleshy, and have but few fibres; so that unless great care be taken, all the earth will fall away from them, which often causes their stalks to decay almost to the root, and sometimes occasions the loss of the plants. It must be sparingly watered at all times, but particularly in cold weather, when moisture will cause it to rot in a short time.

5. *Guilandina Dioica*; *Hairy Bonduc*. Unarmed; leaves bipinnate at the base, and tip simply pinnate; stem erect, thirty feet high or more, dividing into many branches, covered with a very smooth bluish ash-coloured bark.—Native of Canada. This sort will live abroad, and is never hurt by frost. It is propagated by cutting off some of the horizontal roots, or by suckers. It requires a light, but not a very moist soil.

6. *Guilandina Gemina*. Prickly; leaves pinnate; calix five-leaved; fruit in pairs; stem shrubby, large, suberect, with many climbing branches, on which are many recurved, scattered prickles; flowers yellow, in compound, loose, terminating racemes; calicine leaflets obtuse, woolly, bell-shaped, spreading; seeds two or three, roundish, shining, ash-coloured, very hard, containing a roundish oily kernel like an almond.—Native of Cochin-china.

Guinea Grass. See *Panicum Maximum*.

Guinea-Hen Weed. See *Petiveria*.

Guinea Pepper. See *Capsicum*.

Guinea Wheat. See *Zea*.

Gum Elastic. See *Iatropa*.

Gum Elemi Tree. See *Amyris*.

Gum Lac. See *Croton Lacciferum*.

Gum Succory. See *Chondrilla*.

Gundelia; a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: common, scarcely any, except the leaves surrounding the compound receptacle. *Corolla*: compound, tubular, uniform; corollules hermaphrodite, five, equal, proper, one-petalled, club-shaped; border bellying, five-cleft, upright. *Stamina*: filaments five, capillary, very short; antheræ cylindric, tubular, long. *Pistil*: germen ovate, immersed in the receptacle, crowned with very small scales, inferior; style filiform, longer than the corolla; stigmas two, revolute. *Pericarp*: none; but the seeds are totally immersed and hid in the receptacle. *Seeds*: solitary, roundish, acuminate, crowned with an obscure rim; the sides are abortive. *Receptacle*: common, conic, covered on every side with partial receptacles, divided by three-cusped chaffs; partial obtusely conic, quadrangular, truncate, with five little pits, one of which is in the centre, the others in the circumference, for the insertion of the five floscules. *Observe*: One central flower hermaphrodite; four marginal male. ESSENTIAL CHARACTER. *Calix*: scarcely any, five-flowered. *Corolla*: tubular, male and hermaphrodite. *Receptacle*: chaffy. *Down*: none.—The only known species is,

1. *Gundelia Tournefortii*. Root perennial, running deep into the ground. Stalks seldom more than a foot and a half high. The under leaves are long, narrow, and serrate, the teeth ending in a spine; the other leaves are broader, irregularly flashed to the midrib, and armed at the points with sharp prickles. It is a milky plant, and has the habit of a thistle. The flowers appear in June, and the seeds ripen in August.—It is propagated by seed, which should be sown in the beginning of March, in a warm dry border of fresh but lean earth, in the place where the plants are designed to

remain. When the plants come up, they must be carefully cleaned from weeds; as they grow large they should be thinned, leaving the plants which are designed to remain about two feet asunder, that they may have room to spread. After this there is no other culture required, but to keep them clear from weeds; and if the frost should prove severe in winter, the plants should be covered with straw or pease-haulm to protect them, but this covering must be withdrawn in mild weather; in two years they will produce their flowers, and will make a fine appearance among other hardy plants in the pleasure garden. The plants lose their stalks and leaves in autumn, but their roots will abide many years.

Gunnera; a genus of the class Gynandria, order Diandria.—**GENERIC CHARACTER.** *Calix*: ament verticilled; scales one-leafed, one-flowered, setaceous, the length of the flower, permanent; perianth none, except the crust of the seed, which has two seeds. *Corolla*: none. *Stamina*: filamenta two, very short, opposite, sitting on the sides of the germen on the outside of the teeth; antheræ oblong. *Pistil*: germen ovate, with two teeth at the tip; styles two, short, subulate, between the teeth of the germen; stigmas simple. *Pericarp*: none. *Seed*: single, ovate, the bark formed from the crust of the perianth. **ESSENTIAL CHARACTER.** *Ament* with one-flowered scales. *Calix* and *Corolla*: none. *Germen*: two-toothed. *Styles*: two. *Seed*: one.—The only species yet discovered is,

1. *Gunnera Perpersa*; *Marsh-Marigold-leaved Gunnera*. Leaves radical, cordate, obtuse, smooth, veined, repand, tooth-crenate, with the petioles scarcely pubescent; scapes two feet high; ament terminating, long, compound; the subdivisions scattered, simple, distinct; bractes lanceolate, short; floscules naked.—Native of the Cape of Good Hope.

Gustavia; a genus of the class Monadelphica, order Polyandria.—**GENERIC CHARACTER.** *Calix*: none, but the receptacle above surrounded with a rim, flat, broad, bald. *Corolla*: petals six or eight, slightly connected at the base, ovate, sessile, large. *Stamina*: filamenta very numerous, shorter than the petals, uniting at the base into an upright bell, distant from the style; antheræ small, oblong, shorter by half than the petals. *Pistil*: germen turbinate, inferior, flat, bald between the petals and the style; style conical, very short, permanent; stigma blunt. *Pericarp*: berry subglobular, subconical, truncate, six-celled, crowned with the rim of the receptacle. *Seeds*: beans several, oval, smooth, mutilated on one side at the base, with a cartilaginous twisted appendix. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: several. *Berry*: many-celled. *Seeds* appendiced.—The only known species is,

1. *Gustavia Augusta*. This tree has thickish branches, and is from twenty to thirty feet high. Leaves alternate, subsessile, somewhat crowded, in the upper part broad-lanceolate, narrower at the base, from a span to a foot in length, ribbed, subserrate, smooth on both sides. Peduncles from one to three, terminating, bearing one flower, and having one joint. Flower very specious, like the white water-lilly, with a large, naked, bald disk or receptacle between the corolla and the style: petals white, with red tips, the consistence of the white lilly, which it resembles in smell; but the wood is extremely fetid, even after it is dry: the inhabitants use it for hoops.—Native of Surinam and the island of Cayenne.

Gutta. See *Cambogia*.

Gymnanthes; a genus of the class Monœcia, order Monadelphica.—**GENERIC CHARACTER.** **MALE FLOWERS.** *Calix*: ament compound, with pedicels tripartite, or trichotomous, anther-bearing. *Corolla*: none. *Stamina*: fila-

menta naked, on pedicels tripartite, or trichotomous, scattered, placed on every side of the ament, very short, deciduous; antheræ oblong, minute, three-celled. *Female flowers*: on the same, or a different shrub, solitary or amentaceous. *Calix*: perianth none, but one or two scales at the base of the germen. *Corolla*: none. *Pistil*: germen roundish, superior; styles scarcely any or very short, three-cornered; stigmas three, linear, acute, channelled, reflex. *Pericarp*: capsule, triccous, three-celled, three-valved. *Seeds*: solitary, roundish. **ESSENTIAL CHARACTER.** *Male*: ament naked. *Perianth* and *corolla*: none. *Stamina*: pedicels three-parted, or three-forked; anther-bearing. *Female*: ament or germen pedicelled. *Corolla*: none. *Style*: trifid; capsule, triccous, three-celled.—The species are,

1. *Gymnanthes Elliptica*. Dioicous; stamina trichotomous; females amentaceous.—Native of Jamaica.

2. *Gymnanthes Lucida*. Monoicous; stamina trichotomous; females solitary, pedicelled.—Native of Hispaniola.

Gynopogon; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, very small, half-five-clefts, permanent; segments linear, acute, erect. *Corolla*: monopetalous, contorted; tube cylindrical, ventricose below the tip, contracted at the throat; border flat, five-parted; segment ovate. *Stamina*: filamenta five, very short, inserted into the tube above the middle; antheræ erect, linear, within the tube. *Pistil*: germen ovate; style filiform, shorter by half than the tube; stigma globular, two-lobed, villose at the tip. *Pericarp*: berry pedicelled, subglobular, coriaceous, filled with the seed. *Seeds*: single, cartilaginous, subbilocular; with one or two kernels. *Observe*: The fruit is generally abortive, the seed not having kernels: the germina when cut through have two cells, and two seeds in each cell. **ESSENTIAL CHARACTER.** *Calix*: half-five-cleft, inferior, permanent. *Corolla*: five-parted, tube ventricose below the tip; throat contracted; stigma globular, two-lobed; berry pedicelled, subglobular. *Seed*: cartilaginous, subbilocular.—The species are,

1. *Gynopogon Stellatum*. Leaves in whorls, three together, lanceolate.—Native of the Society and Friendly Islands, in the South Seas.

2. *Gynopogon Alyzia*. Leaves in whorls, five together, obovate.—Native of Norfolk Island.

3. *Gynopogon Scandens*. Leaves opposite, ovate, ribbed.—Native of Otaheite.

Gypsophila; a genus of the class Decandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth bell-shaped, angular, five-parted; leaflets ovate, permanent. *Corolla*: petals five, ovate, obtuse, spreading, subsessile. *Stamina*: filamenta subulate, spreading; antheræ roundish. *Pistil*: germen almost globular; styles filiform, gaping; stigmas simple. *Pericarp*: capsule globular, one-celled, five-valved. *Seeds*: very many, roundish. **ESSENTIAL CHARACTER.** *Calix*: one-leafed, bell-shaped, angular. *Petals*: five, ovate, sessile; capsule globular, one-celled, five-valved. *Seeds*: very many, roundish. *Observe*: The third species is dioicous. **ESSENTIAL CHARACTER.** *Calix*: one-leafed, bell-shaped, angular. *Petals*: five, ovate, sessile; capsule, globular, one-celled. The plants of this genus, possessing no great beauty, are rarely cultivated, except in botanic gardens. They are propagated by seeds, sown in a bed of light earth, and when the plants are fit to remove, they may be transplanted into the places where they are designed to remain, and will require no other culture, but to keep them clean from weeds; for the roots of most sorts will continue several years, and annually produce flowers and seeds.—The species are,

1. *Gypsophila Repens*; *Creeping Gypsophila*. Leaves

lanceolate; stamina shorter than the emarginate corolla. The whole plant is smooth; root perennial, woody, very long, as thick as the little finger; stems many, in a close tuft, spread every way, half a foot in length, perennial; flowers remote, few, on bifid or trifid peduncles; corolla white or red, spreading very much; petals flat, a little attenuated towards the base, more or less emarginate, twice as long as the calix; capsules blunt. It flowers in September, and is a native of Siberia, Austria, Switzerland, and Provence.

2. *Gypsophila Prostrata*; *Trailing Gypsophila*. Leaves lanceolate, smooth, and even; stalks diffused; pistils longer than the bell-shaped corolla; root perennial; stems several, smooth, round, about a foot in length, reddish at the joints; corolla white.—It flowers from June to September, and is supposed to inhabit the mountainous parts of Europe.

3. *Gypsophila Paniculata*; *Panicled Gypsophila*. Leaves linear, lanceolate, the lower ones scabrous; stamina minute; styles longer than the corolla; root perennial, thick, fleshy; stems several, round, jointed, prostrate, a foot and a half long, the thickness of a quill, below villose and rugged, four-cornered, and simple, above smooth; flowers very numerous, and without scent; petals white, oblong, blunt, quite entire, twice as long as the calix. It flowers in July and August.—Native of Hungary, Siberia, and Tartary.

4. *Gypsophila Viscosa*; *Clammy Gypsophila*. Leaves ovate-lanceolate, smooth and even, at the base cordate and clasping; the internodes of the branches clammy in the middle; petals retuse; root annual, slender; stem erect, slender, branched almost from the bottom, from a span to a foot high; the whole plant very smooth and glaucous; flowers the size of those in the first and second species; corolla scarcely red, twice as long as the calix, without scent; petals oblong, emarginate.—Native of the Levant.

5. *Gypsophila Ascendens*. Leaves lanceolate-linear; stalks prostrate; corolla, stamina, and pistils, all of the same length; root perennial, whitish, branched, and woody; stems very many, round, smooth, much jointed, leafy, herbaceous, purple at the base, and procumbent; the ascending styles slender, awl-shaped.—Native country unknown.

6. *Gypsophila Altissima*; *Upright Gypsophila*. Leaves lanceolate, three-nerved; stalks straight.—It is perennial, flowers in July, and a native of Siberia.

7. *Gypsophila Struthium*; *Shrubby Gypsophila*. Leaves linear, fleshy, axillary, crowded, columnar; stem shrubby at the bottom, with leafy rudiments from the axiles of the leaves, which are longer than the internodes, and acute at the end;

flowers in corymbs, white, with white ovate petals.—The ancients used this plant instead of soap, and it still answers this purpose in some parts of Spain, where it naturally grows.

8. *Gypsophila Fastigiata*; *Triangular-leaved Gypsophila*. Leaves lanceolate-linear, obscurely three-cornered, smooth and even, obtuse, directed one way; root perennial, very long, the thickness of a finger, white, woody; stalks several, stiff, jointed, smooth, more than a foot long, branched, ending in a dense fastigate cyme of flowers; petals pale rose-colour. Linneus observes, that in Sweden the flowers are always white, and fastigate, in its wild state; the root, like that of the foregoing species, has a saponaceous quality, and, boiled with linen or woollen, may be used instead of soap: it is bitter, and has a solvent aperient quality.—Native of Germany, Sweden, Switzerland, Siberia, &c. It flowers from June to August.

9. *Gypsophila Perfoliata*; *Perfoliate Gypsophila*. Leaves ovate-lanceolate, half-stem-clasping; root perennial, strong, flashy, striking deep into the ground, sending up stalks two and three feet in height, as thick as the little finger at bottom, swelling at the joints, branching at short intervals from top to bottom; flowers numerous, before they expand purple, but becoming paler, and at length white; capsule obtusely four-cornered, four-valved. It flowers in July and August.—Native of Spain and the Levant.

10. *Gypsophila Muralis*; *Wall Gypsophila*. Leaves linear, flat; calixes leafless; stalk dichotomous; petals cranate; root annual, slender, small; stalk diffused, a span in length, weak, and therefore seldom upright. The flowers come out at the divisions of the stalk, singly, on setaceous peduncles, one at the end. In England it flowers from June to October.—Native of Lapland, Sweden, Germany, Switzerland, France, and Siberia.

11. *Gypsophila Rigida*. Leaves linear, flat; stalk dichotomous; peduncles two-flowered; petals emarginate. From a very fibrous root spring numerous little stems, not more than a span high, jointed, branched; flowers pale red.—Native of the south of France, and Siberia.

12. *Gypsophila Saxifraga*; *Small Gypsophila*. Leaves linear; calixes angular, with four scales; corollas emarginate; root perennial, woody, branched; stalks in tufts, procumbent, a span long, or about nine inches, in length, very much branched, bent, and changing their direction at every joint; flowers on long peduncles, on the extreme subdivisions, which are almost naked; petals emarginate, white, with rose-coloured lines. It flowers in July and August.—Native of France, Switzerland, Austria, and Carniola.

H Æ M

HÆMANTHUS; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre six-leaved, very large, bearing an umbellule; leaflets erect, oblong, permanent. *Corolla*: monopetalous, erect, six-parted; parts erect, linear; tube very short, angular. *Stamina*: filamenta six, subulate, inserted into the tube, and longer than the corolla; antheræ incumbent, oblong. *Pistil*: germen inferior; style simple, length of the stamina; stigma simple. *Pericarp*: berry roundish, three-celled. *Seeds*: solitary, three-cornered. ESSENTIAL CHARACTER. Involucre six-leaved, many flowered. *Corolla*: six parted, superior; berry three-celled.—The species are,

1. *Hæmanthus Coccineus*; *Scarlet Hæmanthus*, or *Blood-flower*. Leaves tongue-shaped, flat, smooth and even, pressed close to the ground, in two rows; unbel contracted, fastigate,

H Æ M

shorter than the involucre; border patulous; root large and bulbous, from which the leaves issue. The flowers are produced in autumn, just before the new leaves come out; they are of a bright red, in a large cluster, two or three inches from the bulb.—Native of the Cape of Good Hope. This and the seventh species are not easily propagated in Europe, because their roots do not produce a sufficient quantity of offsets; hence the Dutch gardeners obtain their supplies from the Cape of Good Hope. They will not bear the open air of England during winter; the roots must therefore be planted in a pot filled with light loamy earth, and in the winter should be placed in a dry glass-case, where, during that season, the leaves will be in full vigour, and make a pretty appearance, when intermixed with other plants in the stove. Although they seldom flower here, they deserve a place in every garden

where there is a convenience for keeping them: the roots may be taken up when the leaves are decayed, and kept out of the ground till August, when they should be new potted, and may remain abroad till the end of September, at which time they may be removed into the glass-case; they will require frequent waterings, while growing, but must never have them in large quantities. If a border be made against the front of the greenhouse or stoves, which may be contrived so as to be covered with glasses in winter, in which these roots, with those of the African *Gladiolus*, *Ixia*, Persian *Cyclamen*, &c. are planted in the full ground, they will flower more constantly, and the foot-stalks will rise much higher than those kept in pots.

2. *Hæmanthus Puniceus*; *Waved-leaved Hæmanthus*, or *Blood-flower*. Leaves oblong, elliptic, acute, retuse, waved; umbel contracted, fastigate; border and stamina erect; roots composed of many thick fleshy tubers, forming a head, out of which arises a fleshy spotted stalk, spreading at top into several spear-shaped leaves, which are waved on their edges; stalks a foot high. From the side of the stalk, near the ground, breaks out a strong fleshy scape, six or eight inches long, with a large cluster of yellowish red flowers at the top. —Native of Africa. This plant was first brought to Holland, from whence it has been dispersed all over Europe. It may be propagated by parting the roots; the best time for this is in the spring, before the plants put out new stalks, which is also the proper season for shifting and new potting them; but as the roots do not multiply very fast in offsets, the best way is to propagate them from seeds, which they ripen plentifully in England: the seeds should be sown soon after they become ripe, in pots filled with light earth, and kept in the stove all the winter: if these pots be plunged into the tan-bed in the bark-stove, in the vacancies between the plants, the earth will be kept warm, and will not dry so fast, as when they are placed in a dry stove, while the seeds will be the sooner prepared to vegetate. In the spring the pots may be taken out of the store, and plunged into a hot-bed, which will bring up the plants: they must have air admitted to them every day in mild weather, to prevent their drawing up weak; and when they are fit to remove, they may be each planted in a separate small pot filled with light earth, and plunged into the hot-bed again, to promote their taking new root; then they must be gradually hardened, and afterwards may be removed into the dry-stove, where they should constantly remain, otherwise the plants will not thrive and flower in this country. They must be sparingly watered in winter, for their roots, being fleshy and succulent, are apt to rot with moisture. In summer, during warm weather, they require a large share of air, and frequent waterings, especially when they are in flower.

3. *Hæmanthus Pubescens*; *Downy-leaved Hæmanthus*. Leaves oblong-lanceolate, hirsute on every side; umbel fastigate, rounded; border and stamina erect. It flowers in August, and is a native of the Cape of Good Hope.

4. *Hæmanthus Ciliaris*; *Fringed Hæmanthus*. Leaves lanceolate, smooth, ciliate; involucre broad, shorter than the rounded umbel; border reflex. —Native of the Cape of Good Hope.

5. *Hæmanthus Toxicarius*; *Fan-leaved Hæmanthus*. Leaves in two rows, oblong, flattish, smooth; peduncles longer than the spathe and flower; flowers flesh-coloured. —Native of the Cape.

6. *Hæmanthus Spiralis*; *Spiral-stalked Hæmanthus*. Leaves bristle-shaped; scape filiform, at the base spiral and flexuose; involucre subulate, shorter than the umbel, which bears from one to four flowers. It flowers here in September. —Native of the Cape of Good Hope.

7. *Hæmanthus Carinatus*. Leaves linear, keeled. This species has a large bulbous root, sending out three or four leaves, a foot long or more, not flat, but hollowed like the keel of a boat, and more erect than those of the first sort, but not quite so broad; the flowers are of a paler red. —Native of the Cape of Good Hope. For its propagation, see the first species.

8. *Hæmanthus Multiflorus*; *Many-flowered Hæmanthus*, or *Blood-flower*. Leaves three together, ovate-lanceolate, acuminate, keeled, waved, upright; umbel close, globular; petals spreading; bulb from one to three inches in diameter, the upper parts tinged of a red colour, and speckled like the stalk; scape from eight to eighteen inches in height, speckled with dark red almost to the top, round or flattened, sometimes fluted on one side; corolla of a clear shining blood-red colour, divided to the bottom into six narrow parts, which are pointed, and spread out wide; the leaves stand in some plants nearly as high as the bottom of the flowers, in others as high as the top, or even higher, and do not display themselves entirely till after the flowers are passed.

Hæmatoxylum; a genus of the class Decandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth one-leaved, coloured; tube very short, pitcher-shaped, fleshy, permanent; horder five-parted, spreading, deciduous; parts oblong, blunt; the four upper ones equal, the lowest a little longer than the rest. *Corolla*: petals five, lanceolate, broadest at top, blunt, veined, spreading, nearly equal, inserted into the calix, and larger than its divisions. *Stamina*: filamenta ten, subulate, hairy at bottom on the inside, upright, unequal, scarcely longer than the corolla, inserted into the calix; antheræ oval, small. *Pistil*: germen oblong, sabre-shaped, compressed; style capillary, bent at the tip, longer than the stamina; stigma funnel-shaped. *Pericarp*: legume lanceolate, flat, blunt, one-celled, edged on each side with a thickish suture that does not open, opening by the bursting of the valves in the middle longitudinally, and dividing into two unequal boat-shaped parts. *Seeds*: few, oblong, compressed, furrowed, fixed to one of the sutures. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Legume*: lanceolate; valves boat-shaped. —The only known species is,

1. *Hæmatoxylum Campechianum*; *Logwood*, *Bloodwood*, *Campeache Wood*. The stem rises from sixteen to twenty-four feet high, is generally crooked, and seldom thicker than a man's thigh; branches subdivided, flexuose, prickly, round, ash-coloured; leaves pinnate, petioles alternate, patulous, round, smooth; leaflets four pair on very short petiolules, generally obcordate, entire, small, veined, very smooth and shining, spreading in the day-time, but at night upright, converging; flowers peduncled, numerous, small, pale, yellow, on short, scattered, simple, coloured peduncles. The flowers appear in March and April, and the seeds ripen in July. This tree grows naturally in the bay of Campeache, at Honduras, and in other parts of the Spanish West Indies. It was first propagated in Jamaica, in the year 1715, from seeds brought from the bay of Campeache, and it now grows wild in the neighbourhood of Savannah la Mar, in such quantities as to be extremely inconvenient to the landholders, occupying that district in the same manner as the *Opoponax* and *Cashew* have the southern parts of Middlesex county. It was first introduced to prevent the necessity of forming a settlement upon the Spanish Main; but the result did not fully answer the benevolent intentions of those who first cultivated it. It makes an impenetrable and beautiful fence. The smaller stems are made into hoops. Both the bark and gum are gentle, substringents, but the last excels, and adds a sweetness

to its virtue, which makes it more agreeable to the palate; the inner bark is red, and the wood hard. The wood, says Hill, is a very powerful medicine, to stop fluxes of the belly, and overflowings of the menses: the best way of giving it is in form of an extract, which is to be made by boiling down a strong decoction of it to the consistence of honey; in this form it will keep a long time, and is always ready for use. A strong decoction of this wood, says Meyrich, is found very efficacious for stopping obstinate purges, without contracting the fibres, as the common astringents do: it sheathes and blunts acrimonious humours, and has more of a balsamic than an astringent taste: it strengthens the stomach and bowels, and indeed the general habit, and is an agreeable medicine to take, being free from any thing disgusting to the taste, and almost void of smell: the decoction is made by boiling three ounces of powdered logwood in four pints of water, till it comes to a quart, and then adding about two drachms of cinnamon, which must be allowed to boil together with the logwood a few minutes longer; then, after letting it cool, the liquor must be strained off for use, and may be taken to the amount of three or four ounces, three or four times a day. This decoction is equally agreeable, mild, and safe, and has this advantage attending it, that it may be administered with equal safety, whether the disorder be attended with a fever or not: it commonly tinges the stools, and sometimes the urine, of a deep reddish purple colour; of which circumstance the patient ought to be apprised, that he may not alarm himself, by supposing the colour of the discharge owing to blood. Logwood is a well-known ingredient in dyeing: stuffs, however, would take only a slight and fading colour from logwood, if they were not previously prepared with alum and tartar; a little of the former is also added to the bath, and by these means a tolerably good violet colour is produced. A blue colour may be obtained from this wood, by mixing verdigris with the bath, and dipping the cloth till it has acquired the shade which is desired: the grand use of logwood, however, is for blacks, to which it gives a lustre and velvet cast, and for grays of certain shades: it is also of very extensive use for different compound colours, which it would be difficult to obtain of equal beauty and variety by means of drugs affording a dye of greater permanency. It is used for dyeing silk, violet; for this the silk must be scoured, alumed, and washed, because without the alum it would only take a reddish tinge that would not stand wetting. To dye silk thus, it must be turned in a cold decoction of logwood, till it has acquired the proper colour: if the decoction were used while hot, the colour would be in stripes very uneven. Bergman has observed, that a fine violet might be produced from logwood, by impregnating the silk with solution of tin; in fact we may thus obtain, particularly by mixing logwood and Brazilwood in various proportions, a great number of fine shades, more or less inclined to red, from the lilac to the violet hue.—The seeds of this tree are frequently brought from America, and when fresh will grow readily, if sown upon a good hot-bed; if the bed be kept in a moderate temperature they will grow to be upwards of a foot high in the first year: while the plants are young they are generally well furnished with leaves, in which they are often afterwards very deficient, making but little progress. They are very tender, and should be constantly kept in the bark-stove, where, if duly watered, and the stove be kept in a due degree of heat, they may be easily preserved. In the West Indies, it thrives best in low swampy lands, or shallow waters, or a rich and tolerably firm soil.

Hair Grass. See *Aira*.

Halbert Weed. See *Calea Lobata*.

Halesia; a genus of the class Dodecandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, very small, superior, four-toothed, permanent. *Corolla*: monopetalous, bell-shaped, ventricose; mouth four-lobed, blunt, patulous. *Stamina*: filamenta twelve, seldom sixteen, subulate, upright, a little shorter than the corolla; antheræ oblong, blunt, upright. *Pistil*: germen oblong, inferior; style filiform, longer than the corolla; stigma simple. *Pericarp*: nut corticate, oblong, narrowing to both ends, four-cornered, the corners membranaceous, two-celled. *Seeds*: solitary. **ESSENTIAL CHARACTER.** *Calix*: four-toothed; superior. *Corolla*: four-cleft; nut quadrangular, with two seeds.—The plants of this species are propagated by seeds, when they can be procured fresh from the places of their natural growth; they should be sown in pots as soon as they arrive, placing the pots in the ground where they may only have the morning sun: the seeds often remain a year in the ground; therefore the earth in the pots should not be disturbed, until there be no probability that the seeds will grow. When the plants come up, screen them from the sun, and water them frequently, but sparingly. In the following autumn, the pots should be placed in a common frame, where the plants may enjoy the free air in mild weather, and be screened from frost: in the succeeding spring, and before they begin to shoot, they should each be put into a small pot, plunging the pots in a frame shaded from the sun. In the third spring they may be turned out of the pots, and planted where they are to remain.—The species are,

1. *Halesia Tetraptera*; *Four-winged Halesia*, or *Snowdrop Tree*. Leaves lanceolate-ovate; petioles glandular. This tree frequently comes up with two or three stems, from fifteen to twenty feet high, sending out branches towards their tops; the flower hanging in small bunches, all along the branches, each gem producing from four to eight or nine; they are of a pure snowy whiteness; and as they blow early in the spring, before the leaves appear, and continue for two or three weeks, they make a most elegant appearance; the flowers are succeeded by a tolerably large four-winged fruit, hanging also in bunches, and very agreeable to the taste. The wood is hard and veined; and the bark of a darkish colour, with many irregular shallow fissures. It flowers in April and May.—Native of South Carolina, on the banks of the Santee river.

2. *Halesia Diptera*; *Two-winged Halesia*. Leaves ovate; petioles smooth and even; fruit mucronate, with two large wings opposite to each other, and two minute.—Native of Georgia, on the banks of the Savannah river.

3. *Halesia Parviflora*. Flowers small.—Found in Florida, near Matanza.

Halleria; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, trifid, flat, spreading, very obtuse, permanent; the upper cleft twice as broad as the rest. *Corolla*: monopetalous, ringent; tube roundish at the base, bent in with a swelling throat; border upright, oblique, four-cleft, the upper cleft a little longer than the others, blunt, emarginate; the side ones shorter, broader, sharper; the lowest very short, very slender, and very sharp. *Stamina*: filamenta four, bristle-shaped, straight, inserted into the tube, longer than the corolla; antheræ, roundish, twin. *Pistil*: germen inferior, ovate, ending in a style longer than the stamina; stigma simple. *Pericarp*: berry roundish, two-celled. *Seeds*: small, flat, roundish, winged. **ESSENTIAL CHARACTER.** *Calix*: trifid. *Corolla*: quadrifid. *Filamenta*: longer than the corolla; berry inferior, two-celled.—The only species known is,

1. *Halleria Lucida*; *African Fly-Honeysuckle*. This plant grows to the height of six or eight feet, with a woody stem, well furnished with branches; leaves ovate, serrate, opposite, and continuing green through the year; the flowers come out singly, and are of a red colour, but being intermixed with the leaves, and growing scatteringly on the branches, are not easily discerned; they come out in June, and the seeds ripen in September.—Native of the Cape of Good Hope. It may be propagated, by cuttings; which, if planted in June, in pots of light earth, will soon take root: the plants may be exposed in summer, and will require plenty of water at that season; in the winter they must be housed with the myrtles, and other hardy exotics, which require much air in mild weather.

Halm, or *Helme*. See *Arundo Arenaria*.

Haloragis; a genus of the class Octandria, order Tetragynia.—GENERIC CHARACTER. *Calix*: perianth quadrid, superior, fattened about the germen, permanent. *Corolla*: petals four, oblong, blunt, concave, spreading, with narrow claws, inserted into the calix. *Stamina*: filamenta eight, filiform, upright, shorter than the corolla, inserted into the calix; antheræ oblong, four-furrowed, upright. *Pistil*: germen inferior; styles four, upright; stigmas simple, blunt. *Pericarp*: drupe dry, roundish, crowned with the permanent calix. *Seed*: nut bony, four-celled, with one kernel in each cell. ESSENTIAL CHARACTER. *Calix*: four-cleft, superior. *Petals*: four. *Drupe*: dry, inclosing a four-celled nut.—The species are,

1. *Haloragis Prostrata*. Leaves oblong, quite entire, mucronate; fruits globular; branches four-cornered, smooth; fruits axillary, solitary, pedicelled: when the fruit is in a state of maturity, the plant greatly resembles the *Ammannia Latifolia*.—Native of Botany island near New Caledonia, and found in the isle of Pines in the South Seas.

2. *Haloragis Cercordia*. Leaves serrate; flowers in whorls. The plant is about two feet high, branched, panicled, and upright; stalk quadrangular, and red; the angles elevated, rounded, scabrous.—Native of New Zealand.

Hamamelis; a genus of the class Tetrandria, order Digynia.—GENERIC CHARACTER. *Calix*: involucre three-leaved, three-flowered; the two inner leaflets roundish, smaller, blunt; the outmost larger, lanceolate; perianth double; the outer two-leaved, smaller, roundish; the inner four-leaved, upright: the leaflets oblong, blunt, equal. *Corolla*: petals four, linear, equal, very long, blunt, reflex; nectary of four truncate leaflets, growing to the corolla. *Stamina*: filamenta four, linear, shorter than the calix; antheræa two-horned, bent in. *Pistil*: germen ovate, villose, ending in two styles, which are of the same length with the stamina; stigmas capitate. *Pericarp*: none. *Seed*: nut ovate, half covered with the calix, blunt, furrowed on both sides at the tip, having two little horns, spreading horizontally, two-celled, two-valved. ESSENTIAL CHARACTER. *Involucre*: three-leaved. *Perianth*: four-leaved. *Petals*: four. *Nut*: two-horned, two-celled.—The species are,

1. *Hamamelis Virginica*; *Witch-Hazel*. This tree has a woody stem, from two to three feet high, sending out many slender branches; leaves oval, indented on their edges, having great resemblance to those of the hazel, and placed alternately on the branches: these leaves fall away in autumn, and then the flowers come out in clusters, from the joints; but are not followed by seeds in England. The Indians consider this tree as a valuable article in their materia medica; they apply the bark, which is sedative and discutient, to painful tumours and external inflammations. A cataplasm of the inner rind is said to be very efficacious in

removing painful inflammations from the eyes.—This plant is propagated by laying down the young branches in autumn; they will take root in a year, if sufficiently watered in dry weather. Many of the plants in our gardens have been produced from seeds imported from America: these seeds always remain a whole year in the ground, so that they should be sown in pots for the convenience of plunging them into the earth in a shady part of the garden, where they may remain all the summer, and will only require to be kept free from weeds, and to be watered in very dry weather. In autumn the pots may be removed to a warmer situation, and plunged into the ground under a warm hedge; and if the winter should prove severe, they should have some light covering thrown over the pots, which will secure the seeds from being destroyed. In the spring the plants will come up; therefore as the season grows warm, the pots may be removed where they may have the morning sun till eleven o'clock, and if occasionally watered in dry weather, the plants will have made good progress by autumn, when they should be transplanted, either into small pots, or in a nursery-bed, where in one, or at most two years time, they will be strong enough to plant where they are designed to remain. They delight in a moist soil, and a shady situation.

2. *Hamamelis Macrophylla*. Leaves large, punctated on their lower side with rough tubercles.—Found on the banks of a river in the western part of Georgia.

Hamelia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, acute, very small, superior, upright, permanent. *Corolla*: monopetalous; tube five-cornered, very long; border five-parted, equal small, acute. *Stamina*: filamenta subulate, inserted at the middle of the corolla; antheræ oblong, linear, the same length with the corolla. *Pistil*: germen ovate, with a conical tip, inferior; style filiform, the same length with the corolla; stigma linear, blunt. *Pericarp*: berry oval, furrowed, five-celled, crowned. *Seeds*: very many, roundish, compressed, very small. ESSENTIAL CHARACTER. *Corolla*: five-cleft. *Berry*: five-celled, inferior many-seeded.—The species are,

1. *Hamelia Patens*. Racemes terminating, coloured; leaves ternate, villose, pubescent. This is a shrub, or small tree, growing five or six feet high. Branches diverging, spreading, round, smooth; petioles coloured; the midrib red; flowers directed one way, subsessile, distant, bright-red or scarlet.—Native of the hedges and mountains of Hispaniola. This plant is propagated by seeds when they can be procured fresh from the country where it naturally grows. They should be sown in small pots, and plunged into a moderate hot-bed. The plants generally appear in five or six weeks, and should then be treated in the same way as other plants from the same countries; admitting air in warm weather, and gently refreshing them with water. When fit to transplant, they should be each planted in a small pot, plunging them into the hot-bed again, where they must be shaded from the sun until they have taken new root, when they should have air and moisture according to the warmth of the season. In autumn they must be removed into the tan-stove, plunging the pots into the bed, where they should be always continued: they flower in July, and make a pretty appearance. As the seeds are seldom brought to England, the plant may be propagated by cuttings, which, if planted in small pots, plunged into a moderate hot-bed, and closely covered with either bell or hand-glasses, will put out roots in about six weeks, and may then be treated in the same way as the seedling plants.

Hartogia; a genus of the class Tetrandia, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-cleft, smooth, permanent; clefts acute, very short. *Corolla*: petals four, ovate, obtuse, spreading. *Stamina*: filamenta four, very short, inserted into the base of the germen; antheræ ovate, furrowed. *Pistil*: germen superior, ovate, smooth; style simple, subulate; stigma acute. *Pericarp*: drupe juiceless, ovate, smooth, or a little roughish, scarcely as big as a hazel nut. *Seed*: nut with two seeds somewhat fleshy. **ESSENTIAL CHARACTER.** *Calix*: five-cleft; petals four, spreading. *Drupe*: ovate, inclosing two seeds.—The only species is,

1. *Hartogia Capensis*. This is a tree with oblong, serrate, blunt, smooth leaves. The flowers are axillary, minute, pedicelled.—Found in the woods near the Cape of Good Hope.

Hart-Root. See *Athamanta Cervaria*.

Hart's-Tongue. See *Asplenium Scolopendrium*.

Hart-Wort. See *Tordylium*.

Hasel. See *Corylus*.

Hassagay-Tree. See *Curtisia*.

Hasselquistia; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel spreading; umbellules ten, five of which are in the circumference, the rudiment of the central umbellule is a mortified vitiated body, pedicelled, somewhat three-sided, fleshy, depressed, dark-coloured, hoary above, with white hair; involucre very small, five-leaved, subulate, reflex; involucels halved; those of the outer ones three-leaved, subulate, nodding, shorter than the umbellule; umbel, when fruit-bearing, converging. *Corolla*: flowers radiate, even of the inner umbellules; floscules of the ray hermaphrodite; petals unequal, bowed in, and bifid; the outmost petal two-cleft, and the next single one large, so that in each corollule there are four clefts large, and six small; floscules of the inner disk male; petals nearly equal, bowed in, and bifid, all the clefts small. *Stamina*: filamenta five to all the floscules, longer than the smaller petals; antheræ roundish. *Pistil*: germen inferior; styles filiform, permanent; stigmas obtuse. *Pericarp*: none. *Seeds*: outmost double, oval, smooth, the edge thicker, crenulate; inner solitary, hemispherical, drooping, pitcher-shaped, with the side hollow; these are also furnished with two styles; in the inner disk none.—**ESSENTIAL CHARACTER.** *Corolla*: radiated in the disk, male. *Seeds*: in the circumference double, with a notched edge; in the disk solitary, pitcher-shaped, hemispherical.—The species are,

1. *Hasselquistia Egyptiaca*; *Egyptian Hasselquistia*. Leaves pinnate; leaflets pinatifid; root fusiform, smaller than the finger, white, annual; stem a foot and half high, upright, round, white, with rough hairs, finally muricate, scabrous; umbels of flowers at the top of the stem, and at the ends of all the branches; peduncle five-cornered, muricate; corolla white; antheræ greenish; stamina and styles white.—Native of Egypt, where it flowers in July. This and the next are biennial plants, and being natives of warm countries are with difficulty preserved in England; for when the plants come up early in the spring, they do not perfect their seeds in the same year; and those plants which arise in autumn seldom survive the winter. The surest method therefore to procure good seeds in this country, is to sow them in pots about the middle of August, placing the pots where they may only have the morning sun, and taking care to water, weed,

and thin them. In October remove the pots into a common frame, where they may enjoy the free air in mild weather, but be screened from frost. The spring following, if the plants are carefully turned out of the pots, and planted in the full ground, they will flower in June, and ripen their seeds in August.

2. *Hasselquistia Cordata*; *Heart-leaved Hasselquistia*. Leaves heart-shaped; stem upright, flexuose, a little streaked, hairy at bottom; umbel copious, flat, white, without the central body; marginal petals of the umbellules two, larger, flat, obovate; the rest nearly equal, small, ovate, entire.—For its propagation and culture see the preceding species.

Heath, Sea. See *Frankenia*.

Hebenstreitia; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, membranaceous, emarginate, gaping longitudinally underneath. *Corolla*: monopetalous, one-lipped; tube cylindric, longer than the calix, gaping on the lower side half way; border ascending, flattish, quadrifid, the clefts nearly equal. *Stamina*: filamenta four, of which the upper pair is inserted into the edge of the corolla under the throat, and stands out, the lower anterior pair is bent back to the sides; antheræ crescent-shaped, compressed, truncate outwards. *Pistil*: germen very small; style filiform, flexuose, bent back through the fissure of the corolla; stigma simple. *Pericarp*: capsule oblong, one-celled, two-valved. *Seeds*: two, oblong, convex on one side, three-furrowed, flat on the other. **ESSENTIAL CHARACTER.** *Calix*: emarginate, cleft underneath. *Corolla*: one-lipped, lip ascending, four-cleft. *Stamina*: inserted into the edge of the border of the corolla. *Capsule*: containing two seeds.—The species are,

1. *Hebenstreitia Dentata*; *Tooth-leaved Hebenstreitia*. Leaves linear, toothed; spikes smooth; stalks upright, a foot high, with simple ascending branches next the root, and under the spike; corolla white, with a red throat; singular in having the stamina placed on the very edge of the fissure. Seeds subelliptic, acuminate at the tip, slightly emarginate at the base, pale straw-colour, fixed to the bottom of the capsule, without any receptacle. The flowers are destitute of scent in the morning, at noon they are stinking and nauseous, in the evening ambrosial like the Oriental Hyacinth. Biennial, flowering from February to November.—Native of the Cape of Good Hope.

2. *Hebenstreitia Ciliata*. Leaves linear, toothed; calices three-valved, ciliate. This plant bears a strong resemblance to the preceding species.—Native of the Cape of Good Hope.

3. *Hebenstreitia Integrifolia*; *Entire-leaved Hebenstreitia*. Leaves linear, quite entire. This appears to be a mere variety of the foregoing species.—Native of the Cape of Good Hope.

4. *Hebenstreitia Cordata*; *Heart-leaved Hebenstreitia*. Leaves somewhat fleshy, cordate sessile. This is an under-shrub. Stem upright, whitish, smooth and even, sparingly branched only at top. Spike terminating, sessile. Corolla white, with a flesh-coloured throat. Antheræ compressed, yellow.—Native of the Cape of Good Hope.

5. *Hebenstreitia Erinoides*. Leaves oblong, serrate, hairy; bractes entire, hispid.—Native of the Cape of Good Hope.

6. *Hebenstreitia Fruticosa*; *Shrubby Hebenstreitia*. Leaves lanceolate, toothed, smooth; bractes entire; stem shrubby. —Native of the Cape of Good Hope.

Hedera; a genus of the class Pentandria, order Monogynia.

—GENERIC CHARACTER. *Calix*: involucre of a simple umbel, very small, many-toothed; perianth very small, five-toothed, surrounding the germen. *Corolla*: petals five, oblong, spreading, with the tips bowed inwards. *Stamina*: filamenta five, subulate, upright, of the same length with the corolla; antheræ trifid at the base, incumbent. *Pistil*: germen turbinate, surrounded by the receptacle; style simple, very short; stigma simple. *Pericarp*: berry globular, one-celled. *Seeds*: five large, gibbous on one side, angular on the other. **ESSENTIAL CHARACTER.** *Petals*: five, oblong. *Berry*: five-seeded, surrounded by the calix.—The different species are easily propagated by their trailing branches, which send forth roots of their whole length; or by cuttings, planted on a shady border in autumn, which by the following autumn will be fit to plant where they are designed to remain; or by seeds sown after they are ripe, which is in the beginning of April: if these be kept moist and shaded, they will grow the same spring, otherwise they will remain a year in the ground.—The species are,

1. *Hedera Helix*; *Common Ivy*. Leaves ovate and lobed. The trunk in old trees is covered with an ash-coloured chopped bark; in the young branches it is of a green or purple colour. The petioles are long, and dilated at the base. The flowers yellowish or greenish white, in a very close thick umbel, at the extremities of the twigs. The berry is placed below the receptacle of the flower, and is crowned with the five-cornered streaked rudiment of it; at first it is succulent with a purple juice, afterwards it becomes coriaceous, dry, and very obscurely quinquangular. The seeds are wrinkled and yellowish. The wood is soft and porous, so as to transmit liquids if turned of a sufficient degree of thinness. The roots are used by leather-cutters to whet their knives upon. The branches, being very full of leaves, are as effectual as any thing to protect the tender blossoms of apricots, peaches, and nectarines, against the cold winds and frosts of February and March. As a medicine it is scarcely admitted into modern practice. The leaves have a nauseous taste. Haller says, they are given in Germany as a specific in the atrophy of children. Common people apply them to issues and corns. The berries have a little acidity, and when taken inwardly purge and vomit. In Galicia they give the seeds bruised in pleurisies, to the quantity of two tea spoonfuls every eight hours. In warm climates a resinous juice exudes from the stalks, or may be procured by wounding them. It is insipid and inodorous, but inflames in burning, with a pleasant aromatic smell, and then has a slight astringency. It tinges spirit of wine of a reddish brown colour, and is said to be aperient, resolute, and balsamic: but it is not in use. Country people apply the berries to issues to increase the discharge. Meyrick informs us, that a decoction of the leaves destroys vermin in the heads of children, and heals the soreness which they occasion. An infusion of the berries will sometimes both purge and vomit, in which there is no danger. These berries are frequently found serviceable in rheumatic complaints, and are reported to have cured the dropsy. The juice snuffed up the nose occasions a pretty considerable discharge of mucus and watery humours from the head.—In the latter part of the last century, when it was the fashion to fill gardens with all sorts of sheared evergreens, many of these plants were trained into round heads, clipped into globes, cones, &c. and, being so hardy as not to be injured by weather, and growing in any soil, were then much esteemed: since this

taste has been exploded, the ivy is seldom admitted into gardens, unless to cover walls, or to run over ruins, for which purpose no other plant is so well adapted. Mr. Curtis observes, that few people are acquainted with the beauty of ivy when suffered to run up in a stalk, and at length to form itself into a standard; the singular complication of its branches, and the vivid hue of its leaves, give it one of the first places amongst evergreens in a shrubbery. In woods, when suffered to grow large and rampant, this plant, by twining round the bodies of timber-trees, does them great damage, and therefore should be carefully destroyed, as it easily may be by cutting any where through its trunk. But in ornamental outlets where evergreens do not abound, a few trees covered with ivy have a very pleasing effect, and induce birds of song to haunt those thickets for the sake of the berries and shelter. It produces very picturesque effects in large masses of ruined buildings: but that it is injurious to buildings cannot be denied, when we consider that it must harbour wet and filth, and that the branches will make their way into any fissure or defect in the wall, and enlarge it. It is a parasitical shrub, and while fixed to any support, or left to trail upon the ground, the stalks are slender and flexible; but when it has reached to the top of its support, they shorten and become woody, forming themselves into large bushy heads. As long as the stalks are suffered to trail, ivy does not produce any flowers; and in this state it is called *Barren* or *Creeping Ivy*: but when the branches get above their support, they produce flowers at the end of every shoot; these are succeeded by berries, formed into round bunches, called by the ancients *Corymbi*, and turning black before they are ripe. In this state it is called *Climbing* or *Berried Ivy*. It is found wild all over Europe, but Linneus informs us it is by no means common in Sweden. Kalm remarks, that he never saw the common ivy in North America, except once against a stone building, and that it was apparently brought from Europe and planted there. Thunberg observed it in Japan, and says that the leaves are commonly undivided there, and not lobed. It begins to flower with us in September, and is much resorted to by bees and flies, when little other food is to be had. The berries increase during the winter, are full formed in February, and ripen in April; furnishing food for wild pigeons, black-birds, thrushes and other birds in the spring. Black-birds build their nests in the stump. Sheep are fond of ivy, which is a warm and wholesome food for them in hard weather; and hence in snowy seasons the shepherds cut down the boughs for their flocks to browse on, which is a very ancient practice.

2. *Hedera Capitata*; *Cluster-flowered Ivy*. Leave elliptical, entire; racemes compound, terminating; flowers sessile, in little heads; stem arborescent, eight feet high in the stove, erect, cylindrical, abruptly branched; bark brown, a little cracked; branches curved upwards, leafy, terminated by flowers, which are numerous, white, and so small that the structure is not readily to be understood; each stands on its proper involucre, resembling a calix of one leaf, in five divisions, externally powdery, permanent. This fine plant was discovered by Jacquin in the woods of Martinico.

3. *Hedera Quinquifolia*; *Five-leaved Ivy*. Leaves quinate, ovate, serrate; racemes trifid, twice dichotomous, fine, umbelled; calix very short, bluntly toothed, red at tip; petals blunt, arched at the tip, green. It grows naturally in all the northern parts of America, was first brought to Europe from Canada, and has been chiefly employed to cover walls or high buildings; which this plant will do in a short time, for it will shoot almost twenty feet in one year; but as the leaves fall off in autumn, and are late before they come out

in the spring, it is not much esteemed, unless where better things will not thrive. As it receives no injury from smoke, or the closeness of the air, it is proper to cover buildings in great towns. The stalks put out fibres, like the common ivy, which insinuate themselves into the joints of a wall. It was cultivated here in 1629.

4. *Hedera Pendula*. Leaves ovate-lanceolate, entire; peduncles very long, pendulous.—Native of Jamaica.

5. *Hedera Nutans*. Leaves elliptic, coriaceous; jumbels nodding, hemispherical.—Native of Jamaica.

6. *Hedera Terebinthinacea*. Leaves in sevens, elliptic, quite entire. The whole plant is smooth; branches round, subherbaceous, the thickness of a swan's quill; petioles a span long, round, embracing with the widened base; the middle petiolules two inches long, the side ones shorter; calix a very short entire rim.—Native of Ceylon.

Hedge Hyssop. See *Gratiola*.

Hedge Mustard. See *Sisymbrium* and *Erysimum*.

Hedge Nettle. See *Galeopsis*.

Hedges.—Hedges are either planted to make fences round inclosures, or to part off and divide the several portions of a garden: when they are designed as outward fences, they are planted either with hawthorn, crabs, or black-thorn, which is the sloe; but those hedges which are planted in gardens, either to surround wilderness quarters, or to screen the other parts of a garden from sight, are planted with various sorts of plants, according to the fancy of the owner; some preferring evergreen hedges, in which case the holly is best, next the yew, then laurel, laurustinus, phillyrea, &c. others, who make choice of the deciduous plants, prefer the beech and hornbeam, English elm, or the alder, to any other. Those hedges which are intended for outside fences are generally made of quick; yet it will be proper, before planting, to consider the nature of the land, and what sorts of plants will thrive best in that soil, whether it be clay, gravel, or sand; and also what the soil is from whence the plants are to be taken: for if the land they are taken from be much better than that in which they are to be planted, it will be more difficult to get them to grow. As for the size, the sets ought to be about as large as a goose quill, and cut within about four or five inches of the ground; they should be fresh taken up, straight, smooth, and well rooted. Those plants which are raised in the nursery are to be preferred to all others, and if raised upon a spot near the place will be the best. The time for planting is February, March, and April. Secondly, if the hedge have a ditch, it should be made six feet wide at top, and one foot and a half at bottom, and three feet deep, that each side may have a proper slope; for when the banks are made too upright, they are very subject to fall down after every frost or hard rain: besides, if the ditches are made narrower, they are soon choked up in autumn by the falling leaves, and the growth of weeds, nor are they a sufficient fence to the hedge against cattle where they are narrower. Thirdly, if the bank be without a ditch, the sets should be placed in two rows almost perpendicular, at the distance of a foot from each other in the quincunx order, so that in effect they will be but six inches asunder. Fourthly, the turf should be laid with the grass side downwards, on that side of the ditch the bank is designed to be made, and some of the best mould should be laid upon it, to bed the quick; then the quick is to be planted upon it about a foot asunder so that the ends may stand upright. Fifthly, when the first row of quick is planted, it must be covered with mould, and the turf laid upon it as before; so that when the bank is a foot high you may plant another row of sets against the spaces of the lower quick, covering them as before. The

bank is to be topped with the bottom of the ditch, and a dry or dead hedge laid on the other side, to defend the plantation from cattle. In the making of these dead hedges there should be stakes driven into the loose earth, at about two feet and a half distance, so low as to reach the firm ground: for this purpose oaken stakes are most esteemed, and next to them the blackthorn and willow. The small bushes must be laid at the bottom, but not too thickly, which would cause the bushes to rot; but the upper part of the hedges should be laid with long bushes, to bind the stakes in with, by interweaving them. In order to render the hedge yet stronger, you may edder it, as it is called, that is, bind the top of the stakes in with long small poles, or sticks on each side; and when the eddering is finished, drive the stakes anew, because the waving of the hedge and eddering is liable to loosen the stakes. The quick must be constantly kept weeded, and secured from being cropped by the cattle, and in February it will be proper to cut it within an inch of the ground, if it was not done before; which will cause it to shoot strong, and greatly adjust its growth. When a hedge is of about eight or nine years growth, it will be proper to plash it; the best time for this work is either in October or February. When a hedge is grown old, say about twenty or thirty years growth, and there are in it old stubs as well as new shoots, the old stubs should be cut sloping off within two or three inches of the ground, and the best and longest of the middle size should be left to lay down; and some of the strongest, at the height of five or six feet, in proportion to the intended height of the hedge, may be left to serve instead of stakes, and fresh stakes should be put into those places where they are wanting. The hedge should then be thinned, so as to leave on the stubs only such shoots as are designed to be of use, that there may be room left to put a spade in between them; the ditch also should be cleansed, and each side of the slopes kept as in a new ditch, and where the earth is washed from the roots of the quick, or is hollow, face it anew with so much of the first spit of earth that is dug out of the ditch, as there is occasion for, and lay what is dug out at the second spit, on the top of the bank; for if it be laid on the side or face of the bank, it will slip into the ditch again when wet comes, and also take a great deal of the bank along with it. In plashing quicks there are two extremes to be avoided; the first is laying it too low and too thick, because it makes the sap run all into the shoots, and leaves the plashes without nourishment, which with the thickness of the hedge kills them. Secondly, it must not be laid too high, because this draws all the sap into the plashes, and so causes but small shoots at the bottom, and makes the hedge so thin, that it will neither hinder the cattle from going through, nor from cropping of it. When the shoot that is designed to be plashed is bent, give it a small cut with a bill, half through, sloping a little downwards, and then weave it about the stakes; and when the whole is finished, train off the small superfluous branches that straggle too far out on both sides of the hedge. If the shrubs be very old, cut them quite down, and secure them with good dead hedges on both sides, till the young shoots are got up tall enough to plash, and plant new sets in the void spaces. In making a hedge, if it be set with crab stock, it will be proper to leave one standing uncut up at every thirty or forty feet, if the ground on both sides of the hedge be your own; which being done, they may be so ordered, by pruning or staking, that one may lean into one ground and the other into another. These stocks should be pruned up every year, till they are brought out of the reach of the cattle, and then they may be grafted with the red-streak, geonet-moile, or whatever kind of cyder

apple the planter may prefer. If the stocks be of apple kernels, they may stand ungrafted, for many of them will yield very good cyder fruit; but then such stocks as are not grafted will be longer before they bear, and also when you do graft, you may be certain of your kind; but if you find a very natural stock, which by leaf, shoot, and bud, appears likely, you may try it, and so you may procure a fine new fruit; and if you do not like it, you may graft it when you please. With respect to the rest of the hedge, when it has shot four or five years, you may lay it to make a fence: for the doing of which, take the following directions; first, at every laying, to lay down some old plashes, or, if the hedge be thin, young ones; but they may be so laid, as to point with their ends to the ditch side of the bank, the ends being kept low on the bank; by being so ordered, they will the better thicken the bottom of the hedge, and keep up the earth of the bank. Secondly, to heighten the bank every time you lay earth on it, so as to cover the layers, all but the ends; this earth will very much help the quick, and by heightening the banks, and deepening the ditch, you will render the fence the better. Thirdly, not to cut the plashes too much, but just so as they may bend down well; not to lay them too upright, as some do, but to lay them near to a level; for by so doing, the sap will the better break out at several places, and not run so much to the ends, as it will when they lie too much upon the slope. If you have much wood to spare, you may cut up great part of those that grow near the ditch, but then the banks should be hung with bushes, to prevent cattle from cropping them during the first year; these will shoot strong, secure the hedge, keep up the bank, and thicken the bottom of the hedge. Fourthly, take care to lay the hedge pretty thick, and turn the beard on the ditch-side; but you must not let the beard hang uncut, though it makes a good shew at the first making, but you must cut off all the straggling boughs within half a foot of the hedge on both sides, which will cause it to shoot strong at these places, and make the hedge much thicker. Fifthly, if the bank be high, the hedge should be made so low that it may just serve for a fence the first year, for it will soon grow higher; and the lower the hedge is made, the faster the quick will grow, and also will be thicker at the bottom; but care must be taken to preserve it from cattle, on the field-side, for the first two years that it is made. Sixthly, if you would have a good hedge, or fence, you should new lay it once in fourteen or fifteen years, and constantly root out elder, traveller's joy, which some call bull-bine, briony, &c. and do not leave too many high standards or pollards in it, though the elm is one of the best; also no dead wood is to be left in the bottom of the hedges, for that will choke the quick; but if there be a gap, the dead hedge should be made at a distance. —The crab is also frequently planted for hedges, and if the plants are raised from the kernels of the small wild crab, they are much to be preferred to those which are raised from kernels of all sorts of apples without distinction; because the plants of the true small crab never shoot so strong as those of apples, and may therefore be better kept within the proper compass of a hedge; and as they generally have more thorns upon them, they are better guarded against cattle; besides, the plants of the crab will grow more equal than those which are raised from the kernels of various kinds of apples, for these always produce a variety of plants which differ from each other in their manner of growth, as much as in the size and flavour of their fruits, so that hedges formed of them will neither appear so well, nor can be so well managed as the other. Some persons intermix crab with the white-thorn in their hedges; but this is not a good method,

for the plants of the crab will grow much stronger than those of the white-thorn, so that the hedges will not be of equal growth; which is not near so beautiful or useful, as when the plants of a hedge keep pace in their growth. The black-thorn or sloe is also frequently planted for hedges, and is a strong durable plant for that purpose, especially as it is so strongly armed with thorns, that cattle seldom care to browse upon it: but where this is planted, the best way is to raise the plant from the stones of the fruit; for all those which are taken from the roots of old trees, spawn and put out suckers in such plenty from their roots, as to spread over, and fill the neighbouring ground to a considerable distance on each side of the hedges; and this plenty of suckers drawing away the nourishment from the old plants of the hedge, they never grow so well as where there are few or no suckers produced; which the plants propagated from stones seldom send forth, or at least but sparingly, and therefore they are easily removed. The best method of raising these hedges is, to sow the stones in the place where the hedge is intended, when it can be conveniently done, for then the plants will make much greater progress than those which are transplanted: but the objection to this method will arise from the difficulty of securing the young plants from the cattle; yet this can have little force, when it must be considered, that if the hedge be planted it must be fenced for some years, to prevent the cattle from destroying the sets; therefore the same fence will do for it when sown, nor will it require a fence much longer than the other, for the plants which stand unremoved, will make a better fence in seven years, than that which is transplanted when the plants be of three or four years growth. The stones of this fruit should be sown early in January, if the weather will permit; but when they are kept out of the ground longer, it will be proper to mix them with sand, and keep them in a cool place. The bushes of the black-thorn are by much the best of any for making of dead hedges, being more lasting, and having so many thorns, that neither the cattle nor the hedge-breakers will care to meddle with it. They are also the best to be used for underground drains, for the draining of land; for they will remain sound a long time, after the air is excluded from them. —The holly is sometimes planted for hedges, and is a very strong and durable fence; but where it is exposed there will be great care necessary to prevent it from being destroyed. It is by far the most beautiful plant that is used for hedges, and being an evergreen will afford much better shelter in winter than any other kind of hedge, especially as the leaves are armed with thorns, which prevent the cattle from browsing on it. This plant however is of slow growth, so that hedges planted with it require to be fenced a much longer time than most others. This defect will exclude it from general use: yet in such grounds as lie contiguous to or in sight of gentlemen's houses, hedges of holly will have a very pleasing effect, especially where they are well kept, as they will preserve their beauty at all seasons; and in the spring of the year, when the sharp winds render it unpleasant to walk abroad, these hedges will afford a good shelter for keeping off the cold winds. The surest method of raising a holly hedge is, by sowing the berries in the place where they are to stand; but these berries should be buried in the ground a whole year before they are sown; by which method they will be prepared to grow in the following spring. The way of doing this, is to gather the berries about Christmas, which is the time they are usually ripe, and put them into large flower pots, mixing some sand with them; then dig holes in the ground, into which the pots must be sunk, covering them over with

earth about ten inches thick; in this place they remain till the following October, and should then be taken up to be sown wherever the hedge is to be raised. The ground for this hedge ought to be well trenched, and cleared from the roots of all bad weeds, bushes, and trees. Two drills should then be made about a foot distance from each other, and about two inches deep, into which the seeds should be scattered pretty close, lest some should fail; for it is better to have too many plants come up than to feel a deficiency. When the plants come up they must be carefully weeded, for if the weeds be permitted to grow among them, they will soon destroy or weaken them so much, that they will not recover their strength in a long time. This should be constantly observed by every person who is desirous to have good hedges of either sort; for when the weeds are suffered to grow near the plants, they will not only rob them of a great part of their nourishment, but also prevent them from putting out shoots near the ground, which will cause the bottom of the hedge to be thin and naked. When holly hedges are intended to be kept very near, they should be sheared twice a year, in May and August; but if they are merely employed as fences, they will not require shearing more than once a year, which should be about the latter end of June, or the beginning of July; and if this be well performed, the hedges may be kept in a very orderly state. The fences which are made to secure these hedges from cattle while they are young, should be contrived to admit as much free air as possible, for that is absolutely necessary for the growth of the plants, which seldom thrive well when crowded on each side with dead hedges. The best sort of fences for this purpose, are those which are made with posts and rails; or, instead of rails, three ropes drawn from post to post through holes in each post. This is the cheapest fence of this kind, and will appear very handsome; but where the sheep are not admitted into the fields only two ropes will be required to keep off larger cattle. If the ropes be well besmeared with a composition of melted pitch, brown Spanish colour, and oil, mixed well together, they will last sound several years; and these sorts of fences never obstruct the air, while the place being at the same time open to view, the weeds will be more easily discovered than where the fences are close. In the latter case, the hedges are sometimes suffered to be overrun with weeds, by their being excluded from sight, and are frequently forgotten, especially in moist weather, when the weeds grow most luxuriantly. There are some persons who intermix holly with the white-thorn in making their hedges, which will have a good effect when rightly managed, especially when young; but when this is practised, the holly should be planted so near as that the hedge may be entirely formed of it as it grows up, when the white-thorn should be quite rooted out; for as they will not keep pace in their growth, they cannot appear to advantage where they remain intermixed. When a hedge of holly is intended to be made by plants, the ground should be well branched, as has been already advised for the seeds; and unless the soil be very wet the plants should be set in October, but in wet grounds March is preferable. These plants should by no means be taken from a better soil than that in which they are to be replanted, for then they are often longer before they recover from the change than those which are taken from a leaner soil. If the plants have been removed two or three times before, they will have better roots, and will be in less danger of miscarrying; besides, they may be removed with balls of earth to their roots. When the frost comes on, if mulch be laid upon the ground near the roots of the plants, it will prevent the tender fibres, which may then have been put out, from being destroyed by the

cold. We would never advise the planting of hedges with holly plants of above five or six years growth from the berries; for when the plants are older, if they take to grow, they are longer before they form a good hedge, than plants which are much younger; and if the plants have been twice before transplanted, they will more certainly grow.—Ornamental hedges, such as are used in gardens, are sometimes planted with evergreens, especially if they are not intended to grow very high, for then they are planted with deciduous trees. Evergreen hedges are formed from holly, yew, laurel, *laurustinus*, *phillyrea*, *alaternus*, evergreen oak, and some others of less note. The holly is preferable to any other, for the reasons above advanced.—Next to this, most persons prefer yew, on account of its growing very close; for when these hedges are well kept, they will be so thick as that a bird cannot get through them; but the dead colour of the yew renders these hedges less agreeable to the eye.—The laurel is one of the most beautiful greens of any of the evergreen trees; but then it shoots so luxuriantly as to make it difficult to keep hedges planted with it in any tolerable shape; besides, the leaves being very large, will be often clipped with the shears when the hedge is dressed, which gives them a bad appearance: therefore where there are hedges of this kind, it will be the best way to prune them with a knife, cutting the shoots just down to a leaf; and although by this method the hedge cannot be rendered so even as when cut with shears, yet it will preserve a much better appearance than when most of the leaves are cut through and stubbed by the shears.—The *laurustinus* is also a very fine plant for this purpose; but the same objection is to be made to this as has been advanced against the laurel; and as one of the greatest beauties of this plant is in its flowers, which are produced in the winter and spring, so when these are sheared, the flowers are generally cut off, by which their beauty is lost. Nor can this be avoided where the hedge is to be kept in close order, and hence this plant is not so proper for that purpose; but in places where walls and other fences are designed to be hid, there is not any plant better adapted than this, provided it be rightly managed; for the branches of this plant are slender and pliable, so that they may be trained up close to the fence, so as to cover it entirely; and if, instead of clipping it with shears, a pruning knife be employed, they may be so managed as to have them full of flowers from the ground upward. This may be effected by pruning them in April, when the flowers are going off, cutting out those shoots that have flowered, or project too far from the fence, always cutting close to the leaf, that no stubs may be left; but those new shoots of the same spring must by no means be shortened, because the flowers are always produced at the extremity of the shoots of the same year; therefore when these are topped, as they must be by shearing, there can be few or no flowers upon these plants, except towards the top, where the shears have not passed. By this method of knife-pruning, the leaves will also be preserved entire, and the hedge may always be kept enough within compass, and so thick as fully to answer the purpose of covering the fence; and if the shoots be suffered to grow rather irregularly, it will make a better appearance than any thorn-hedge whatever. The small-leaved and the rough-leaved *laurustinus*, are the best sorts for this purpose, because their branches grow closer together than those of the shining-leaved; they are also hardier, and flower much better in the open air.—The true *phillyria* is the next best plant for hedges. It is called the true *phillyria*, to distinguish it from the *alaternus*, which is simply called the *phillyria*. The branches are strong, the leaves large, and of a deep green colour. It is of middling growth. Hedges planted with this

may be led up to the height of ten or twelve feet; and if these hedges are kept narrow at the top, that there may not be too much width for the snow to lodge upon them, they may be rendered very close and thick, and being of a very good green colour will make a fine appearance. The alaternus was formerly much more cultivated in the English gardens than at present. It was often planted to form hedges; but the branches are too pliable, being frequently displaced by strong winds, which render these hedges unsightly; they also shoot very irregularly and thin, so that the middle of the hedge is frequently open and wide, and only the sides of them can be kept tolerably close, and that must be by often clipping them. If we add to this, their being frequently laid or broken down by snow in the winter, it must be deemed an improper plant for this purpose.—The Ilex or Evergreen-oak is also planted for hedges, and where these are designed to grow pretty tall, it is a fit plant for the purpose, because it is a plant of large growth, especially the sort which is most common in England; for there are two sorts of them, which grow in the south of France and Italy, that are of much humbler growth, and better adapted to this purpose, especially when a high hedge is not wanted; but they are not common in Great Britain. When these hedges are planted very young, and kept close-trained from the beginning, they may be very close from the ground to the height of twenty feet or more, but must always be kept narrower at the top than below, that too much snow may not lodge upon and break them down in the winter.—There are also some persons who have planted the Pyracantha, or Evergreen-thorn, Juniper, Box, Cedar of Virginia, Bay, &c. as also the Halimus, or Sea Purslane, the Furze, the Rosemary, and several other plants, for hedges; but the five sorts first mentioned having very pliant branches, which will require to be supported, and the last being often destroyed by severe frost, are unfit for this purpose; nor are there any other sorts of evergreen plants in the English gardens, which are so well adapted for hedges as those we have already pointed out.—The deciduous trees which are usually planted to form hedges in gardens, are the following sorts: The Hornbeam, which is most esteemed, especially in places where they are not required to be very high, or not wanted to grow very fast; for this plant while young does not make so great progress as many others: as it is of slower growth, the hedges formed of it may be kept neat with less trouble than most other plants will require, and the branches naturally growing very close, they will make one of the closest hedges of all the deciduous trees; but as the leaves of this tree continue upon the branches all the winter, and until the buds in the spring force them off, they have a bad appearance during the winter season. In Westphalia, and other parts of Germany, the hornbeam is in great repute for hedges. The German husbandman throws up a parapet of earth, with a ditch on each side, and plants his sets, raised from layers, in such a manner as that every two plants intersect each other; there he scrapes off the bark, and binds them close together with straw. The plants consolidate, and form a living palisado, which being pruned annually with discretion, will in a few years make an impenetrable fence. It is not uncommon in Germany to see the sides of high-roads thus guarded for many miles together. The hornbeam is not delicate in point of soil; will put out strong lateral shoots within three inches of the ground; and is of quick growth. The Beech is also a very proper tree for this purpose, having the same good qualities as the hornbeam; but the leaves of this continue late in winter upon the branches, when they will have a bad appearance; besides, the litter which is occasioned by their leaves gradually falling most part of the

winter, prevents the garden from being made clean a great while longer than if there were none of these planted. The small-leaved English Elm, is also a proper tree for tall hedges: if these be planted young, and kept closely clipped from their first setting out, the hedges may be trained up to the height of thirty or forty feet, and be very close and thick the whole height. But when these trees are planted for this purpose, they should not be crowded so close together as they generally are; by which method, when the trees have stood some years, if they have thriven well, their stems will approach so near each other as that few branches can be maintained below, whereby the bottom of the hedge will be naked; therefore they should be planted closer together than seven or eight feet, or if they be ten feet it will be still better from the ground upward. The Dutch Elm was formerly in great esteem for hedges, being quick of growth, and thriving in such soils as the English elm would not grow in; but the wretched appearance which these hedges made, after they had been growing a few years, caused them to be very generally discontinued, for a more unsuitable plant was never introduced into gardens. The Lime-tree has also been recommended for hedges, and in some of the old gardens there were many planted with this tree, which, for a few years after planting, made a tolerable appearance, especially when they grew upon a moist soil; but after they had stood some years, they grew very thin at bottom, and by being sheared at the top, they were rendered very stubby and unsightly: their leaves growing very thinly upon the branches, and these frequently turning of a black disagreeable colour, and falling off very soon in the autumn, and sometimes in the summer in dry seasons, has brought these trees into so much disrepute, that few persons at present will make use of them for this purpose: nor should any of the very strong shooting trees be applied to this use; for the more they are cut the stronger they will shoot, and of course will appear very unsightly; besides the often cutting of the hedges occasions great trouble and expence, and frequent litters in gardens. The Alder is frequently planted for hedges, and where the soil is moist, there is not any of the deciduous trees equal to it for this purpose; for the leaves are of a lively green, continuing fresh till late in the autumn; and when they decay their litter is soon over, for they all drop in a short time.—There are, besides the trees above mentioned, many of the flowering shrubs which have been planted to form hedges; such as Roses, Honeysuckles, Sweetbriar, &c. but these make a bad appearance, being more difficult to train; and if they are cut to keep within compass, their flowers, which are their greatest beauty, will be entirely destroyed. But as these are but of low growth, they are not proper to plant where the hedges are to be of any height. The taste in gardening has been greatly improved of late years; clipped hedges have been almost excluded, and it is to be hoped that they will soon be wholly banished, as both troublesome and unnatural.

Hedwigia; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, cup-shaped, four toothed; teeth minute, sharp, upright. *Corolla*: monopetalous, tubulous; tube the length of the calix, narrower at top; border quadrifid; the clefts ovate, sharp, upright, converging. *Stamina*: filamenta eight, broad, inserted into the base of the corolla, incumbent on the germen; antheræ minute, oblong, sharp, converging above the stigma. *Pistil*: germen conical, eight-streaked, superior; style none; stigma blunt. *Pericarp*: tricoccous, (composed as it were of three ovate-acuminate capsules) large, three-celled. *Seeds*: nuts solitary, ovate, acuminate, one side

convex and very smooth, the other wrinkled and unequal; kernels the shape of the nuts. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Corolla*: four-cleft; style none; capsule trilocular. *Seed*: a nut.—The species are,

1. *Hedwigia Balsamifera*. Leaves oval, ending in a lengthened point at top, without any indentations, thin, shining, waved, yellowish green, five or six inches long, and three inches wide, ranged in pairs along a midrib, terminated by an odd one. The flowers grow in a raceme at the extremities of the branchlets, and are white. The fruit is the size of a small nut, divided in two or three parts, covered with a green coriaceous rind, and containing a white fleshy sweet pulp, having an aromatic smell: each division has in it a flattened woody shell, inclosing a bitter oily kernel. This is a lofty tree, growing to the height of more than sixty feet, with a trunk four or five feet in circumference; outer bark grey and even; inner red, thick, and gummy; wood solid and reddish, and is used as timber for various purposes. An aromatic oil is drawn from the kernels, which is much esteemed in disorders of the breast. The red gum that issues from the bark has a strong aromatic smell, and is much used in the cure of wounds. It is supposed that the wild swine first discovered this use of it; and hence it has acquired the name of *Bois Cochon*, or *Hog's wood*.—Native of St. Domingo.

Hedycarya; a genus of the class *Dicæcia Icosandria*.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, flat-wheel-shaped, eight or ten cleft; clefts lanceolate, nearly equal; in the female permanent. *Corolla*: none. *Male*. *Stamina*: filamenta none; antheræ very many, fifty, oblong, four-furrowed, bearded at the tip, distributed along the whole bottom of the calix. *Female*. *Pistil*: germina numerous, flattened-globular, placed each on a cylindric pedicel in the middle of the calix; styles none; stigmas, papillæ scattered over the germina. *Pericarp*. *Seeds*: nuts six or ten, pedicelled, globular, somewhat bony; kernels solitary, globular. *Receptacle*: in the middle of the calix, woody. **ESSENTIAL CHARACTER.** *Calix*: eight or ten cleft. *Corolla*: none. *Male*. Filamenta none; antheræ in the bottom of the calix, four-furrowed, bearded at the tip. *Female*. Germina pedicelled; nuts pedicelled, one-seeded.—The only known species is,

1. *Hedycarya Dentata*. A smooth shrub. Leaves alternate, oblong, serrate, on short petioles, very smooth, veined, the veins almost transverse; racemes axillary; calices hirsute; nuts very sweet.—Native of New Zealand.

Hedycree; a genus of the class *Pentandria*, order *Monogynia*.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, hemispherical, five-toothed; teeth sharp, patulous. *Corolla*: none. *Stamina*: filamenta five, inserted into a ring, surrounding the calix within, below the teeth, opposite to and shorter than they; antheræ roundish. *Pistil*: germen roundish, villose, superior; style longer than the calix, bristle-shaped, villose; stigma blunt. *Pericarp*: drupe oval, soft, fibrous within, one-celled. *Seed*: nut ovate, covered with fibres, one-celled; the shell hard. **ESSENTIAL CHARACTER.** *Calix*: one-leaved, hemispherical, five-toothed. *Corolla*: none; drupe oval, one-celled; nut ovate, covered with fibres, one-celled; the shell hard.—The only species known is,

1. *Hedycree Incana*. The extremities of the branches and twigs have oval leaves, ending in a point, smooth and green on the upper surface, covered with a very white down underneath, and placed alternately; their petiole is short, accompanied at the base by two opposite stipules. The flowers grow in a spike at the ends of the branches and twigs; they are white, close, and sessile. The fruit is the size of a large

olive, white, dotted on the outside with red; the pulp is white, melting, and of a sweetish taste; the shell or nut is bony, and separates with difficulty from the fibres in the pulp; the kernel is two-lobed. This tree grows only to the height of three or four feet, with a trunk five or six inches in diameter. The bark is ash-coloured, very thin, falling in large pieces, and renewing itself every year. The wood is hard, whitish, and when sawed has the smell of rancid oil.—Native of Guiana, where it is called *Caligni* by the natives, who are very fond of the fruit, which is ripe in November and December.

Hedyosmum; a genus of the class *Monoecia Polyandria*.—**GENERIC CHARACTER.** *Male Flowers.* *Calix*: ament without scales, covered on every side with stamens; perianth none. *Corolla*: none. *Stamina*: filamenta none; antheræ very many, imbricately heaped together, upright, oblong, acuminate at the tip, converging at the base into an oblong ament, and placed on a linear receptacle. *Females solitary on the same tree.* *Calix*: perianth one-leaved, covering the germen; three-toothed at the tip; teeth minute, upright. *Corolla*: none. *Pistil*: germen oblong, three-cornered; style short, three-cornered; stigma simple, obtuse. *Pericarp*: berry roundish, three-cornered, small, superior. *Seed*: single, hard, three-sided, shining. **ESSENTIAL CHARACTER.** *Male*. Ament: covered with antheræ. No perianth, corolla, or filamenta. *Female.* *Calix*: three-toothed. *Corolla*: none; style one, three-cornered; berry three-cornered, one-seeded.—The species are,

1. *Hedyosmum Nutans*. Stem shrubby; branches loose; leaves lanceolate, acuminate.—Native of Jamaica,

2. *Hedyosmum Arborescens*. Stem arborescent; branches stiff, upright; leaves ovate-lanceolate.—Native of Jamaica.

Hedyotis; a genus of the class *Tetrandria*, order *Monogynia*.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, four-parted, superior, permanent; parts linear, sharp. *Corolla*: monopetalous, funnel-shaped, a little longer than the calix, half-four-cleft; clefts patulous, nearly equal. *Stamina*: filamenta four, subulate, inserted at the sinuses of the corolla; antheræ roundish. *Pistil*: germen roundish, inferior; style filiform, the length of the stamina; stigmas two, thickish. *Pericarp*: capsule twin-globular, two-celled, gaping next the coronal, calix with a transverse cleft. *Seeds*: few, angular. **ESSENTIAL CHARACTER.** *Corolla*: monopetalous, funnel-shaped. *Capsule*: two-celled, many-seeded, inferior.—The species are,

1. *Hedyotis Maritima*. Leaves oval, blunt; flowers opposite, sessile; stems herbaceous, prostrate, a hand in length, smooth and even; fruit the size of coriander.—Native of the East Indies.

2. *Hedyotis Pumila*. Leaves ovate, sharp; flowers alternate, peduncled; root annual; stems little, branched, a hand in length, smooth and even; peduncles lateral, solitary, capillary, upright, the length of the leaves; capsule roundish, with a groove on each side, crowned with the four teeth of the calix.—Native of Tranquebar.

3. *Hedyotis Fruticosa*. Leaves lanceolate, petioled; corymbs terminating, involucred; stem four-cornered; stipules ovate, rhomboid, broad, short; corymbs brachiate, or trifid; calix four-cleft; style bifid, blunt.—Native of Ceylon.

4. *Hedyotis Auricularia*; *Earwort*. Leaves lanceolate, ovate; flowers in whorls; stems smooth, long; branches long, jointed, alternate; stipules toothed, joining the peduncles; flowers many, in whorls, on very short pedicels from each axil. It is accounted a specific in deafness.—Native of Ceylon.

5. *Hedyotis Herbacea*. Leaves linear-lanceolate; stem herbaceous, dichotomous; peduncles in pairs; stem eight inches high, slender, procumbent; leaves sessile, smooth,

quite entire, opposite; flowers axillary, in pairs, but often solitary; corolla white, subcampanulate; stamina short; stigma oblong, bifid; seeds very numerous.—Native of Ceylon and Cochin-china.

6. *Hedyotis Graminifolia*. Leaves linear; stem decumbent; panicle racemed, with the flowers directed one way; peduncles following the sun; perennial; stems filiform, a foot long; corolla blue; the segments before noon expanding very wide, in the evening two upright, and two bent back; antheræ upright, nearly equal, blue; seeds very minute, numerous.—Native of the East Indies.

7. *Hedyotis Hispidula*. Leaves linear-lanceolate; flowers in whorls; stems half a foot in length, decumbent, quadrangular, hispid, with a branch or two; petioles extremely hispid, united with the filiform torn stipules so as to form a short sheath; pedicels scarcely observable; calix hispid; segments both of that and the corolla sharp; stamina the length of the corolla; style longer, club-shaped; capsule half-two-celled, the partition disappearing in the middle, and not reaching to the tip; seeds many.—Brought from Canton in China.

8. *Hedyotis Rupestris*. Leaves four-faced, awl-shaped, channelled; flowers sessile, axillary; corollas villose, with a crooked tube. This is a shrub, seldom exceeding three feet in height. Branches diffused, often procumbent at the base, otherwise erect. The flowers are yellow, without scent, sessile, axillary, solitary; the germen and part of the corolla is concealed within the sinus of the leaf. There is a single stipule on each side of the germen, of the same length and form, with a calicene leaflet.—Native of Havannah, on rocks near the sea-coast, and of Jamaica.

Hedypnois; a genus of the class Syngenesia, order Polygamia Equalis.—GENERIC CHARACTER. *Calix*: common calicled, cylindrical, ten-leaved or thereabouts, permanent; scales linear, erect, acute, equal; calicled at the base, with fewer, narrower scales, which are short and close. *Corolla*: compound, subimbricate, uniform; corollules hermaphrodite, many. Proper monopetalous, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubulous. *Pistil*: germen oblong; style filiform, length of the stamina; stigmas two, reflex. *Pericarp*: none. Common calix hardened, converging, almost globular, covering the marginal seeds with its scales. *Seeds*: solitary, somewhat oblong, bowed in a little, streaked, roughish, the length of the calix. The outer crowned, with the calicle membranaceous, erectish, obscurely five-cornered, toothletted; pappus none; the inner crowned with the calicle, obscure, many-bristled, very short, within which is a pappus of five erectish awned chaffs. *Receptacle*: naked. ESSENTIAL CHARACTER. *Calix*: calicled, with short scales. *Seeds*: crowned with the calicle; outer without down, covered up in the scales of the calix; inner having a down of five erectish awned chaffs. *Receptacle*: naked, hollow, and dotted.—This genus embraces some species of *Hyoseris* and of *Crepis*; and, according to Jussieu, *Lapsana Zacintha*. For Hudson's species of *Hedypnois*, see *Apargia*. See also *Leontodon* and *Tragopogon*, to which this genus is nearly allied.

Hedysarum; a genus of the class Diadelphia, order Decandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, half-five-cleft; clefts subulate, upright, permanent. *Corolla*: papilionaceous, streaked; banner reflex-compressed, ovate-oblong, emarginate, long; wings oblong, narrower than the other petals, straight; keel straight, compressed, broader outwardly, transversely blunt, from the base to the swelling part bifid. *Stamina*: filamenta diadelphous, simple, and nine-cleft, bent in at a right angle; antheræ roundish, compressed.

Pistil: germen slender, compressed, linear; style subulate, bent in with the stamina; stigma very simple. *Pericarp*: legume with roundish compressed joints, two-valved, and containing one seed. *Seed*: kidney-shaped solitary. *Observe*: The pericarp differing in this genus, has occasioned its being unnaturally separated into several genera. ESSENTIAL CHARACTER. *Corolla*: keel transversely obtuse. *Legume*: jointed, with one seed in each joint.—The species are,

* *With simple leaves.*
1. *Hedysarum Alhagi*; *Prickly Hedysarum*. Leaves lanceolate, obtuse; stem shrubby, thorny, about three feet high, branching out on every side. From under the leaves come out thorns nearly an inch long, of a reddish brown colour. The flowers come out from the side of the branches in small clusters; they are purple in the middle, and reddish about the rims; legumes sickle-shaped.—Native of the Levant. It is on this shrub that manna is found in Mesopotamia and other eastern countries. It is gathered about mount Tauris, where the shrub grows in abundance. It is propagated by seeds, which will frequently lie a year in the ground before they vegetate: sow them therefore in pots filled with light earth, and plunge them into a moderate hot-bed: if the plants do not appear by the beginning of June, take the pots out of the bed, and place them where they may have only the morning sun, and in the autumn plunge them into an old bed of tanner's bark under a frame; in spring plunge them in a fresh hot-bed, which will bring up the plants: when they are fit to remove, put them separately into small pots filled with light earth, and plunge them into a very moderate hot-bed, shading them from the sun till they have taken new root; then gradually inure them to the open air, into which remove them in June, placing them in a sheltered situation, where they may remain till the autumn; when they ought to be plunged into an old tan-bed under a frame, where they may be protected from frost, and in mild weather enjoy the free air. In a warm border, by covering it in frosty weather, this plant will endure our winters when they are not severe.

2. *Hedysarum Bupleurifolium*; *Hare's-ear-leaved Hedysarum*. Leaves lanceolate, acute; stem unarmed; stipules scarious; stipules the length of the petioles; legumes even-jointed, upright, equal. It varies with lanceolate and cordate oblong leaves.—Native of India. This and the seventeen following species are all too tender to endure the open air of our climate. They are propagated by seeds, which must be sown upon a hot-bed early in the spring. When the plants are fit to remove, they must be each planted in a separate small pot, filled with light earth, plunging them into a fresh hot-bed, where they should be screened from the sun, till they have taken new root; after which they may be treated in the same manner as other tender plants; always keeping them in the bark-stove or glass-case, otherwise they will not produce seeds, nor even always flower in England. They require as much air as possible in warm weather. Many of the sorts seldom flower till the second year.

3. *Hedysarum Linifolium*; *Flax-leaved Hedysarum*. Leaves linear, hoary; stem prostrate; legume globular; racemes very short, axillary; legumes small, snow-white, with a permanent style, one-jointed.—Native of the East Indies. For its propagation and culture see the preceding species.

4. *Hedysarum Nummularifolium*; *Moneywort-leaved Hedysarum*. Leaves wedge-shaped; stems long, angular, diffused; stipules awl-shaped, longer than the petiole, patulous, very small, clothing the stem; spikes solitary from the axils, on a long peduncle; flowers very small; the legumes declined, crescent-shaped, hispid on the back, containing one seed.

—Native of the East Indies. For its propagation and culture see the second species.

5. *Hedysarum Moniliferum*; *Lecklace Hedysarum*. Leaves orbiculate; legumes necklace-shaped, globular, jointed; stems a span long, prostrate; stipules two-parted, streaked, sharp, scariose; heads of flowers axillary, perennial.—Native of the East Indies. For its propagation and culture see the second species.

6. *Hedysarum Styracifolium*; *Storax-leaved Hedysarum*. Leaves cordate, orbiculate, retuse, smooth on the upper surface, tomentose underneath; stem shrubby, and like the whole plant villose; stipules lanceolate.—Native of China. For its propagation and culture see the second species.

7. *Hedysarum Reniforme*; *Kidney-leaved Hedysarum*. Leaves kidney-shaped; stem columnar, annual, a foot and a half high, branched, slender, smooth, procumbent; flowers violet-coloured, in terminating spikes or racemes, consisting of few flowers.—Native of India, and the suburbs of Canton in China. For its propagation and culture see the second species.

8. *Hedysarum Sororium*. Leaves kidney-shaped, emarginate; stem three-sided, herbaceous, sarmentose, smooth, a foot high; petiole almost the length of the leaf; stipules two, oval, small, petioled at the base of the petioles, so that the leaves might in strictness be looked upon as ternate.—Native of the East Indies. For its propagation and culture see the second species.

9. *Hedysarum Vespertilionis*; *Bat-winged Hedysarum*. Leaves simple and ternate; middle leaflets two-lobed; lobes lanceolate, divaricate; legumes plaited; stem four feet high, upright, very straight, almost simple, round, but four-cornered at the top, furrowed, hispid, with very fine hairs, frequently having one or two short upright branchlets; flowers in a simple, long, upright, terminating spike, or raceme; corolla white; banner broad, cordate, converging, a little longer than the calix; wings bent in, shorter than the banner; keel of an intermediate length.—It is a native of Siam, from whence it has been carried into Cochinchina, where it is cultivated for its beauty, for in a gentle breeze, the leaves as they move resemble as many variegated butterflies. For its culture and propagation see the preceding species.

10. *Hedysarum Gangeticum*; *Oval-leaved Hedysarum*. Leaves ovate, acute, stipuled. This is an annual plant, about three feet high, having a slender stalk inclining to be shrubby; flowers minute, in long terminating spikes; banner and keel of the corolla yellow; wings violet-coloured.—Native of India and the suburbs of Canton. For its propagation and culture see the second species.

11. *Hedysarum Maculatum*; *Spotted Hedysarum*. Leaves ovate, obtuse; stems several, from a hand to a long span and a foot in height, either upright or declining, round, slender, roughish with slender hairs pressed close; flowers on the upper part of the stalk in pairs one above another, or sometimes three together, on very slender peduncles, forming a long thin spike, in which each pair of flowers is placed in a contrary situation to the next.—Native of the East Indies. For its propagation and culture see the second species.

12. *Hedysarum Latebrosum*. Leaves ovate, serrulate; legumes hid by a vaulted, supine, scariose bracte; stem somewhat shrubby, naked, with few wandlike divaricate round branches; flowers axillary; peduncle very short, two-flowered, with a leafy bracte, resembling a dry wrinkled leaf, and defending the legume from birds.—Native of India. See the second species.

13. *Hedysarum Vaginale*; *Sheathed Hedysarum*. Leaves cordate-lanceolate; petioles simple; stipules sheathing. This

plant is annual, herbaceous, and procumbent; stipules acuminate; spikes towards the ends of the stems long and narrow; branches few; legumes cylindric, smooth-jointed, straight, dividing by joints, though they are scarcely apparent on the outside, and there are no divisions within.—Native of India. See the second species.

14. *Hedysarum Glumaceum*. Leaves simple, lanceolate; stipules and calices scariose; legumes wrinkled; perennial; stems woody, procumbent, wandlike, round, smooth, a foot high; raceme terminating; when in flower two inches long, when in fruit elongated; flowers usually in pairs, seldom solitary.—Native of the Cape of Good Hope. For its culture and propagation see the second species.

15. *Hedysarum Imbricatum*; *Imbricate-leaved Hedysarum*. Leaves cordate, sessile, stipuled, the upper ones imbricate, flower-bearing; stems herbaceous, filiform, diffused, branched; flowers among the upper leaves, solitary, sessile, shorter, hid by the leaves.—Native of the Cape of Good Hope. See the second species.

16. *Hedysarum Triquetrum*; *Triangular-branched Hedysarum*. Leaves oblong; petioles winged; branches three-sided; stems many, perennial, shrubby, procumbent, three feet long; with three side branches; flowers purple, in spikes or racemes, mostly terminating; banner roundish. In the Cochinchinese plant, the leaves have not rounded margins, nor refracted petioles, as the plant of Ceylon has; they have both lanceolate stipules, and the stem inclining to red at the end. The Chinese call it *Kasongso*.—Native of India, China, and Cochinchina. For its propagation and culture see the second species.

17. *Hedysarum Strobiliferum*; *Strobile-bearing Hedysarum*. Bracts of the strobiles inflated, cordate, obtuse. This is a tree with oblong-ovate alternate leaves, quite entire, and petioled; stipules subulate; branches round. There are strobiles from the axils of the leaves, as in the Hornbeam, on a simple flexuose peduncle.—Native of India. For its propagation and culture see the second species.

18. *Hedysarum Gramineum*; *Grass-leaved Hedysarum*. Leaves linear, lanceolate; stipules scariose; racemes naked; pedicels two-flowered; teeth of the calix bearded. This shrub is determinately branched; stems round, stiff, jointed; racemes stiff, elongated, leafless; peduncles in pairs, one-flowered, distant; corolla small, purple.—Native of India. See the second species.

*** With conjugate leaves.

19. *Hedysarum Diphyllum*; *Two leaved Hedysarum*. Leaves binate, petioled; bracts in pairs, ovate, acute, sessile; annual; stems herbaceous, procumbent, filiform, round, smooth; peduncles axillary, terminating, longer than the leaves, upright, stiff, many-flowered; flowers alternate, on very short pedicels, between two opposite bracts, acuminate at both ends; corolla yellow or purple.—Native of Jamaica, South America, and the East Indies.

*** With ternate leaves.

20. *Hedysarum Ascendens*. Leaves roundish, pubescent, underneath; stem columnar; branches declined, ascending, hairy; racemes simple, erect, axillary.—Native of Jamaica.

21. *Hedysarum Pulchellum*. Bracts in pairs, conjugate, orbiculate, marked with lines; stem shrubby, upright, three feet high, round, smooth; branches many, oblique, obtusely angular; spikes of flowers long, straight, terminating; corolla yellow; legume flat, straight, acuminate, composed of two joints defended by the bracts.—Native of India and China.

22. *Hedysarum Elegans*. Leaves obtuse, tomentose on both sides; bracts conjugate, ovate; legumes bowed; stem

somewhat shrubby, upright, three feet high, branched; spikes upright, mostly terminating; flowers heaped, yellow, each with two hairy bractes, marked with lines.—Native of China, near Canton.

23. *Hedysarum Spartium*. Leaves ternate and simple, somewhat tomentose; stem dichotomous; flowers in pairs; legumes jointed, hispid. This is a whitish plant, with shrubby variegated stems, very short blunt stipules, and oblong leaves; flowers scattered, subpedicelled, in pairs or solitary; corolla yellow, with the claw the length of the calix, and the border flat.—Native of India.

24. *Hedysarum Lineatum*. Leaves oblong, marked with lines; racemes axillary, pendulous; stem straight; legumes rhomb-shaped, of one joint only, with one seed.—Native of Ceylon.

25. *Hedysarum Supinum*. Leaves ovate, bluntish, hoary, villous underneath; stem branched, procumbent; racemes simple, erect, terminating; root long, small, woody; stems a foot long, reddish, rough, round, woody; corolla purple; legumes crooked, forming a semicircle, brown, the joints united by so small an isthmus, that when they adhere by their roughness to the clothes, they separate; whence the Portuguese name of *Erya de Amor*, or Love-Herb.—It grows almost every where in the woods of Jamaica.

26. *Hedysarum Canum*. Leaves ovate, acuminate, hoary underneath; stem columnar, branched, erect; racemes terminating, erect; legumes declined, rough with hairs. The stalks are terminated by long spikes of small purple flowers, which are succeeded by narrow pods, straight on one side, but jointed on the other.—Native of Jamaica and Hispaniola.

27. *Hedysarum Retroflexum*. Racemes erect; legumes pendulous, many-jointed, compressed, with one edge repand, and from four to seven joints; leaflets ovate, tomentose, underneath silky.—Native of India.

28. *Hedysarum Trigonum*. Leaves ovate, acute, rough with hairs; stem climbing, three-sided; racemes very long, axillary; legumes writhed, bent in. It is a climber, and raises itself generally to the top of the tallest trees in the wood. The stem is every where beset with small hooked bristles, or rough hairs. The leaves are much like those of the kidney-bean; and all the branches terminate in a large and beautiful flower-spike.—Native of Jamaica.

29. *Hedysarum Umbellatum*. Peduncles umbelliferous; stem shrubby. This shrub has woody branches, the lower ones round and brown, the upper ones angular and villous; peduncles axillary, solitary, shorter than the petioles; flowers white.—Native of India, Tanna, and New Caledonia.

30. *Hedysarum Biarticulatum*. Stem undershrubby; legumes two-jointed; leaves like those of Trefoil, with ovate-oblong smooth leaflets, almost equal; flowers in spikes.—Native of India and China.

31. *Hedysarum Lappaceum*. Leaves ternate, obcordate; flowers axillary, subsolitary; legumes two-jointed, with hooked bristles; stems suffruticose, prostrate, pubescent, round, the thickness of a pigeon's quill, very much branched; stipules minute, awl-shaped; flowers on short peduncles, solitary, seldom two together; germen villous.—Native of the East Indies.

32. *Hedysarum Heterocarpon*. Flowers panicle-spiked; legumes jointed, the lowest one-seeded; stipules bristle-shaped; stems round, hardish; spike of flowers narrow. There is a variety which is more procumbent, with blunter leaflets: the lowest legumes of this are not always one-jointed.—Native of Ceylon, China, Japan, and the Society Isles.

33. *Hedysarum Viscidum*. Legumes membranaceous, even, entire; stem and branches hispid. The upper branches

are hispid, with spreading viscid hairs; leaves on longish petioles; leaflets broad, from round inclined to rhomb-shape.—Native of India.

34. *Hedysarum Scorpiurus*. Leaves oblong, hirsute underneath; stems procumbent, three-cornered; racemes axillary; legumes roundish, upright. This plant grows in tufts, and seldom rises above sixteen or seventeen inches from the root.—Native of Jamaica and Hispaniola.

35. *Hedysarum Canadense*; *Canadian Hedysarum*. Leaves simple and ternate; stem even; flowers racemed. This is an upright plant, and mostly smooth. Stem streaked, and angular; leaflets lanceolate; stipules awl-shaped. It is perennial.—A native of Virginia and Canada, where it is found flowering in July and August.

36. *Hedysarum Gyrens*; *Sensitive Hedysarum*. Leaves oval-lanceolate, obtuse, the lateral ones minute; racemes terminating and axillary, rather simple, many-flowered, long; leaflets pubescent; flowers nodding; bractes solitary, membranaceous, cordate, under the flowers deciduous; calix erect, two-lipped; upper lip trifid, lower with two smaller contiguous teeth; banner of the corolla largish, roundish, entire, brown with dusky streaks; wings connected with the keel by their upper edge, brown; keel longer than the wings, bifid at the base and tip, compressed, ferruginous; legume on a short pedicel, compressed, channelled on the back, crenate in front, gaping, containing five or six kidney-form oblong seeds. The leaves are of a bright green, with the middle part of a more glaucous appearance than the rest. This is a wonderful plant, on account of its voluntary motion, which is not occasioned by any touch, irritation, or movement in the air, as in Mimosa, Oxalis, and Dionæa, nor is it so transitory as in Amorpha. No sooner, says Linneus, had the plants raised from seed acquired their ternate leaves, than they began to be in motion this way and that; this movement did not cease during the whole course of their vegetation, nor were they observant of any time, order, or direction; one leaflet frequently revolved, whilst the other on the same petiole was quiescent; sometimes a few leaflets only were in motion, then almost all of them would be in movement at once: the whole plant was very seldom agitated, and that only during the first year. It continued to move in the stove during the second year of its growth, and was not at rest even in winter. Swartz observes that the motion is irregular, and that it sometimes ceases entirely; that it is immoveable in a very hot day, being only slowly agitated in the evening. In our climate, the leaves in general only make a feeble attempt at exerting this extraordinary faculty towards the middle of the day. We are at a loss to account for this motion, which does not depend upon any external cause that we can trace, and which we are not able to excite by any art that we possess. It is not the action of the sun's rays, for the plant is fond of shade, and the leaves revolve well on rainy days, and during the night; exposed to too much wind or sun, it is quiet. Perhaps, says Linneus, there may be some part in vegetables, as in animals, where the cause of motion resides.—It is a native of Bengal, near the Ganges; and is there called *Buram chadali* or *Burram chandali*. It grows luxuriantly, and flowers, in the gardens at Jamaica. The seeds of this plant may be sown in the beginning of April, in a light fresh earth. When the plants are come two inches high, they should be transplanted where they are to remain for good; but if they are not too thick in the seed-bed, they may be suffered to remain there until the following autumn, at which time they should be carefully taken up, and transplanted into the borders where they are designed to stand; for their roots generally run down very deep, so that

it is unsafe to remove them often. This plant produces its flowers about the same time of the year as the former, and if the season proves favourable, perfects its seeds in autumn; and the roots will abide in the open air very well, resisting the severest cold, provided they be planted in a dry soil.

37. *Hedysarum Canescens*; *Rough-leaved Hedysarum*. Leaves scabrous underneath; stem hispid; flowers racemed, conjugate. This is an upright hairy plant; the leaflets are ovate; stipules awl-shaped, subcordate; flowers white.—Native of Virginia.

38. *Hedysarum Repandum*. Leaves ternate, repand-crenate; racemes terminating, elongated. The stem is also woody, round, purplish, pubescent at top; leaflets on a short petiole, ovate, unequal; petioles two inches long, pubescent, jointed, and thicker at the base, with two bristle-shaped scales between the leaflets; stipules lanceolate, ciliate; peduncle terminating, erect, half a foot long; flowers very remote, purple, before they open drooping; legume linear.—Native of Arabia.

39. *Hedysarum Adhærens*. Leaves ternate, oblong; racemes axillary; legumes cylindric, jointed, villous; stems weak, simple, three-sided, somewhat hairy; leaflets petioled, an inch long, the side ones smaller, having long hairs thinly scattered over both surfaces, and pressed close to them; petioles an inch and a half long, hairy.—Native of the West Indies.

40. *Hedysarum Marilandicum*; *Maryland Hedysarum*. Leaves roundish; stem frutescent, branched very much; legumes jointed, even; root perennial; flower-stems squarish and roughish, with small flowers, distant from each other, in two long rows, on short slender peduncles; corolla purple fading to blue; banner broadish, first concave then spreading, having greenish spots at the base; wings applied to the keel, of a purple colour; keel compressed, whitish towards the base.—Native of Virginia, Carolina, and Maryland.

41. *Hedysarum Tortuosum*; *Twisted-podded Hedysarum*. Leaves oval, oblong, obtuse, smoothish; racemes erect, axillary; legumes twisted, compressed, pubescent. It grows erect, and rises generally to the height of two feet and a half or more; flowers in spikes thinly placed, on pedicels half an inch long; corolla of a pale purple colour.—It is common in the remote hills and inland parts of Jamaica, Santa Cruz, and Vera Cruz.

42. *Hedysarum Spirale*; *Spiral-podded Hedysarum*. Leaves ovate, obtuse, smooth; stem very much branched, with diffused branches; racemes loose, divaricate; legumes spirally twisted; flowers small, of a pale purplish colour.—Native of Jamaica.

43. *Hedysarum Frutescens*. Leaves subovate, villous underneath; stem frutescent; root perennial; flowers at the ends of the branches in short spikes, purplish-yellow and small.—Sent by Dr. Dale from South Carolina. This may be raised in the same manner as directed for the second species. In summer the plants may be exposed to the open air, but in the autumn they must be placed under a frame to screen them from frost; the following spring some of these plants may be shaken out of the pots, and planted in a warm border, where, if the summer prove warm, they will flower, but these seldom perfect their seeds; therefore two or three plants should be put into larger pots, and plunged into a moderate hot-bed, which will bring them early to flower, and if the glasses be kept over them in bad weather, these will ripen their seeds in autumn; and the roots will continue some years, if screened from frost in winter.

44. *Hedysarum Axillare*. Leaves rhombed, roundish;

stem creeping, rooting; petioles upright; scapes axillary, longer than the leaves. This runs many feet from the main roots, commonly casting a few fibres from all the joints that touch the ground, which greatly forwards its luxuriant growth. The leaves are marked with some prominent veins on the under side, and are seldom less than an inch and a half in length.—Commonly found in the shady hills of Jamaica and St. Domingo.

45. *Hedysarum Viridiflorum*; *Green-flowered Hedysarum*. Leaves sharpish; stem upright; racemes very long, upright; perennial.—Native of North America.

46. *Hedysarum Hirtum*. Leaves oval; stem shrubby; spikes oblong; calices and fruits hirsute, one-seeded; spikes oblong; legumes of one joint, ovate, acute. In gardens, the first year it bears mutilated flowers, and yet is fruitful. The second year the corollas are white.—Native of Virginia.

47. *Hedysarum Junceum*; *Slender-branched Hedysarum*. Leaves lanceolate; legumes one-jointed, rhomb-shaped; peduncles subumbelled, lateral; root perennial; stem herbaceous, two feet high, rushy, wand-like, round, somewhat furrowed, smooth, somewhat pubescent towards the end; branches of the same length and structure with the stem, alternate, few; flowers in pairs, erect, pedicelled; corolla white; banner broad, roundish, scarcely emarginate, with blood-red streaks at the base; wings ovate, rounded at the tip; keel bifid from the tip to the middle; the lobes rounded. It flowers in July and August.—Native of India.

48. *Hedysarum Violaceum*; *Violet-flowered Hedysarum*. Leaves ovate; flowers in pairs; legumes naked, veined, jointed, rhomb-shaped; flowers violet-coloured, in pairs, usually connected by their proper pedicels, in some glomerate from the axils of the leaves, in others fixed here and there on filiform peduncles.—Native of North America.

49. *Hedysarum Paniculatum*; *Panicled Hedysarum*. Leaves linear-lanceolate; flowers panicled; legume rhomb-shaped; flowers purple.—Native of Virginia.

50. *Hedysarum Nudiflorum*; *Naked-flowered Hedysarum*. Flowering-stem naked; leafy stem angular; flowers purple.—Native of Virginia.

51. *Hedysarum Repens*; *Creeping Hedysarum*. Leaves obcordate; stems procumbent; racemes lateral; flowers variegated red and white, or sometimes white only, on long axillary upright peduncles, disposed in a small spike; legumes short, acuminate, smooth, compressed, containing one very small ovate seed.—Native of both Indies.

52. *Hedysarum Hamatum*; *Hook-podded Hedysarum*. Leaves nerved, naked; spikes sessile; legumes two-seeded, covered, having a hooked point; root long, deep; stems many, round, hairy, from seven or eight inches to a foot in length, creeping, branched; leaflets small, smooth, shining, ciliate, having many beautiful white nerves on the under surface. The flowers come out towards the top; they are of an orange colour, with a little purple in the middle.—Native of Jamaica, Hispaniola, and Ceylon. There is a variety, the stems of which are from one to two feet in length, shrubby, gray, branched into many twigs, which are green and hoary; leaflets purple on the edge, having purple spots on their backs, and a down of the same colour; petioles half an inch long; flowers on the tops of the twigs, yellow, several opening successively. Swartz makes it a distinct species under the name of *Stylosanthes Viscosa*.—Native of Jamaica and Ceylon.

53. *Hedysarum Triflorum*. Leaves obcordate; stems procumbent; peduncless one-flowered, seldom three together; roots simple, long; flowers minute, scarlet; legume small, peduncled, crenate in front, containing three or four seeds,

which are roundish and minute. It wakes at ten o'clock in the morning, and sleeps at four in the afternoon.—Native of both Indies and China. There is a variety of this species found in Ceylon and China.

54. *Hedysarum Barbatum*; *Bearded Hedysarum*. Racemes oblong, somewhat branched; legumes bent in; calices hairy; stem procumbent, from three to five inches in length, branched, round, somewhat shrubby at the base, even; branches procumbent, almost simple, short, round, pubescent; flowers terminating in a sort of spike, comose; peduncles long, two, approximating, filiform; the flowers nodding, pale blue.—Native of Jamaica, in the dry sandy parts.

55. *Hedysarum Lagopodioides*. Racemes oblong; legumes bent in; calices hirsute; stem undershrubby, upright, two feet high, round, hispid; with diffused branches; flowers dark purple, in oblong, dense, very hirsute, terminating spikes; seeds flattish, brown, even, small.—Native of China and New Caledonia.

56. *Hedysarum Microphyllum*. Leaves ovate, villose; stem frutescent, upright, smooth; flowers terminating, panicled; petioles capillary, purple, smooth; flowers on capillary pedicels, alternate or subdichotomous, flexuose, purple, hispid; corolla purple.—It flowers in August and September, and is a native of Japan.

57. *Hedysarum Racemosum*. Leaves oblong, stipuled, smooth; stem frutescent, upright; racemes axillary, upright, very long; legumes smooth; racemes a hand or more in length, from upright, spreading, capillary, smooth, often several; pedicels solitary or in pairs, one-flowered, very short, capillary.—Native of Japan.

58. *Hedysarum Caudatum*. Leaves oblong, smooth; stem herbaceous; panicle terminating; legumes tomentose; calix hirsute; corolla purple; legume almost linear, with ferruginous down on it.—Native of Japan.

59. *Hedysarum Tomentosum*. Leaves tomentose underneath; stem angular, tomentose; racemes axillary. The whole plant, except the surface of the leaves, is tomentose; stipules two, at the base of the petiole, broad at the base, bristle-shaped.—Native of Japan.

60. *Hedysarum Sericeum*. Leaves emarginate, villose; stem frutescent, upright; flowers axillary, solitary; stipules bristle-shaped; flowers on very short peduncles; calices silky, tomentose. It flowers in September and October.—Native of Japan.

61. *Hedysarum Virgatum*. Leaves obtuse, with a point; stem angular, hairy; peduncles capillary, three-flowered; it is herbaceous, with hairy angles, upright, purplish; branches alternate, filiform, angular, hairy, from erect spreading, wand-like; flowers axillary; peduncles hairy, three-flowered at the tip, from spreading reflex, an inch long.—Native of Japan.

62. *Hedysarum Pilosum*. Leaves ovate, acuminate; stem decumbent, rough with hairs; racemes axillary; each raceme has about four flowers; peduncle capillary, scarcely the length of the petiole; corolla purple. It flowers in September.—Native of Japan.

63. *Hedysarum Striatum*. Leaves oblong, stipuled; stem herbaceous; flowers axillary, solitary; stipules at the base of the petiole, ovate, membranaceous, ferruginous, pressed close; flowers single, on very short peduncles from the axils of the leaves; calix hairy; corolla purplish.—Native of Japan.

64. *Hedysarum Volubile*; *Twining Hedysarum*. Leaves ovate-oblong; stem twining; root perennial; spikes of flowers axillary, on very long, slender, smooth, peduncles; flowers distant, two or three together, generally opposite; banner

broadish, first concave, then flat, and bent back with a greenish spot at the base; wings of a middling length, applied to the keel, which is compressed and cuspidate; the whole of a very lively purple, except in the hidden parts of the banner, which changes to an obscure dun colour.—Native of North America.

65. *Hedysarum Triangulare*. Leaves ovate, acute, marked with lines; umbels axillary; branches three-sided, flexuose. All the nerves underneath, with the midrib above, are very tomentose; flowers small, sessile, in a peduncled axillary umbel; angles of the branches tomentose. Thunberg gathered it in Java.

*** *With pinnate leaves.*

66. *Hedysarum Argentatum*; *Silvery Hedysarum*. Leaflets silky underneath, and shining; legumes jointed; stem leafless; scapes the length of the leaves, or higher, somewhat tomentose, white; spike terminating; calicine leaves near the length of the corolla, which is violet-coloured or white, with the wings shorter than the banner; the legume consists of two or three lanuginous joints, enveloped in the dry flower.—Perennial, and a native of Siberia.

67. *Hedysarum Alpinum*; *Alpine Hedysarum*. Legumes joined, smooth, pendulous; stem upright, somewhat shrubby, round, simple, branched; flowers yellow, in small upright racemes.—Native of Siberia and Cochinchina.

68. *Hedysarum Obscurum*; *Creeping-rooted Hedysarum*. Stipules sheathing; stem upright, flexuose; flowers pendulous; root perennial, creeping; root-leaves on the flowering plant none; flowers eight lines in length, imbricate, pendulous, on short peduncles, varying in number, having no scent; lower segments of the calix gradually longer; corolla violet-purple or red, seldom white; banner spotted with white above the claw; that and the wings nearly of the same length; the keel shorter; germen commonly red.—It flowers on the Higher Alps, of which it is a native, in July.

69. *Hedysarum Coronarium*; *Common Hedysarum*, or *French Honeysuckle*. Legumes jointed; prickly, naked, straight; stem diffused; root biennial. From the angles which the leaves form with the stem and branches, peduncles come out five or six inches in length, sustaining spikes of beautiful red flowers, which open in June and July, and perfect seeds in September, after which the roots commonly decay; but if the plants be cut down before they seed, they will last longer.—It is a native of Spain and Italy. Ray observed it in Sicily. In Calabria it grows wild in great luxuriance, near four feet high, affording excellent nourishment to horses and mules, both green and made into hay, but it does not endure the spring well in the north of Italy: and on that account we may reasonably infer that it could not be profitably cultivated in England. Osbeck mentions, that he saw it brought into Cadiz in great bundles, as food for the cattle. In German, French, Italian, and Spanish, it has the name of *Sulla*; the Germans also call it *Kronencklee*, *Schildklee*, and *Spanische Klee*. The French also use the names of *Sainfoin d'Espagne*, and *Sainfoin à bouquets*; and the Dutch call it *Sierlyk haanekop*. In England it was formerly called *Red Satin-Flower*, or *Red-flowered Fitchling*, as well as *Red* or *French Honeysuckle*, the name it still retains. It may be propagated by sowing the seeds in April, in a bed of light fresh earth; and when the plants come up they should be transplanted into other beds of the like earth, and in an open situation, at about six or eight inches' distance from each other, leaving a path between every four rows, to go between them to hoe and clear them from weeds. In these beds they may remain till Michaelmas, and may be then transplanted into the large borders of a parterre or pleasure garden, allowing

which they should be interspersed, to continue the succession of flowers; where they will make a fine appearance when blown, especially the red sort, which produces very beautiful flowers. As these plants decay after they have perfected their seeds, so there should annually be a fresh supply of plants raised, where they are desired, for the old roots seldom continue longer. They are very proper ornaments for large borders, or to fill up vacancies among shrubs; but they grow too large for small borders, unless their stalks are pruned off, leaving only two or three on each plant, which, if kept upright with sticks, will prevent their hanging over other flowers.

70. *Hedysarum Flexuosum*; *Waved-podded Hedysarum*. Legumes jointed, prickly, flexuose; stem diffused; the stalks rise nearly a foot high, and the leaves are composed of two or three pairs of ovate leaflets, terminated by an odd one. The flowers come out in spikes at the top of the stalks, and are of a pale red intermixed with a little blue. They appear in July, and are succeeded by jointed pods, which are waved on both sides, forming an obtuse angle at each joint; the seeds ripen in autumn.—Native of the Levant. This and the two following species should be sown in April where they are to remain, and require only to be thinned where they are too near, and kept free from weeds.

71. *Hedysarum Humile*; *Dwarf Hedysarum*. Legumes jointed, rough; wings of the corolla obsolete; spikes hirsute; stems depressed; root perennial; stems half a foot in length, usually with one branch and leaf only; leaflets obovate, oblong, villose underneath; spike ovate. It is an annual plant, and flowers in July and August.—Native of the south of France and Spain. For its propagation and culture, see the preceding species.

72. *Hedysarum Spinosissimum*; *Prickly Hedysarum*. Legumes jointed, prickly, tomentose; stem diffused; annual. The legume has generally two orbicular joints equally prickly; the stem is terminated by small spikes of purple flowers, which are succeeded by small rough legumes.—Native of Spain and Portugal. For its propagation and culture, see the seventieth species.

73. *Hedysarum Virginicum*. Stem shrubby; legumes jointed, smooth, peduncled, upright; leaflets oblong, blunt, small, many; flowers violet-coloured, in terminating spikes; legumes slender, with roundish, flattened seeds.—Native of Virginia and Cochinchina.

74. *Hedysarum Fruticosum*. Leaflets alternate, oblong, soft; stipules subulate; racemes axillary; joints of the legumes netted; corollas purple; legumes flattened, with the joints wrinkled and netted. It is a very handsome plant, grateful to horses, and extremely useful in fixing driving sand.—Native of Siberia.

75. *Hedysarum Pumilum*. Stem undershrubby; wings shorter than the banner, and banner shorter than the keel; legumes one-seeded. This is a small shrub only a hand in height. Spike smooth; banner half the length of the keel, which is very large, broad, and blunt; calix even, with very short awl-shaped teeth.—Native of Spain.

76. *Hedysarum Argenteum*. Leaves pinnate; legumes one-seeded, wrinkled; spikes ovate, very hairy; stems erect, hairy; root-leaves simple; petiole elliptic, the next ternate; flowers crowded; cauline peduncles axillary, elongated, higher than the stem, tomentose, hoary at top; corolla purple, half the length of the calix; banner orbiculate; wings minute.—Native of the Levant and Barbary.

77. *Hedysarum Onobrychis*; *Cultivated Hedysarum*, *Sainfoin*, or *Cock's Head*. Legumes one-seeded, prickly; them at least three feet distance from other plants, amongst

wings of the corolla equal in length to the calix; stem elongated; root perennial; peduncles long, slightly hairy, bearing numerous flowers in a long spike, thickly imbricate upwards, each with an awl-shaped bracte, longer than the pedicle; corolla standard oval, slightly emarginate, partly bent back, shorter than the keel, flesh-coloured, striated with red veins; wings not longer than the teeth of the calix, hooked near the base, pale flesh-colour; keel broad, bent with an obtuse angle at the top, flesh-coloured, with a deeper red beneath. It is much cultivated in several parts of Europe, in dry soils, for feeding cattle; and is found in England on Gogmagog hills, Newmarket heath, about Royston in Norfolk, on Salisbury plain, in Cambridgeshire, Hertfordshire, on Epsom downs, Cotswold hills, about Malton in Yorkshire, and generally in all other hilly situations and calcareous soils. It yields great abundance of excellent fodder, but is supposed to be much sooner damaged by rain, when cut, than any other sort of plant usually mown for hay. The old English names were *Medick Vetchling*, or *Cock's Head*. The modern name of *Sainfoin* came from France, whence we originally had the seed. The Germans have many names for it: they call it *Espazette*, *Esper*, *Sparsette*, *der Gemeine Sussklee*, *Hahnenkopf*, *Hahnenkamm*, *Hahnem Kammklee*, *Grosser Turkischer Klee*, *Turkischer Kleberklee*, *Schweizerklee*, *Wickenklee*, *Eselswicken*, *Heiligheu*, *Stachelheu*, *Stachelahre*, *Wiedhopfenkraut*, *Gurtriemen*, *Frauenspiegel*, *rothe Ramsen*, *Sainfoin*: The Dutch call it *Haanekammetje's*; the Swedes and Danes, *Esparsset*, and *Sainfoin*: the French, *Sainfoin*, (*Saintfoin*), *Esparcette*, *Foin de Bourgogne*: the Italians, *Cedrangola*: the Spanish and Portuguese, *Pipirigallo*.—Native of England, France, Flanders; many parts of Germany, as the Palatinate, Bohemia, Silesia; in Austria, Carniola, Switzerland, Savoy, Italy, Spain, Siberia; on hilly pastures, and open downs, particularly in a calcareous soil. If sown upon a dry, gravelly, or chalky soil, will continue eighteen or twenty years; but on a deep moist soil the roots will run down into the ground, and in the winter season the moisture will rot them; so that it seldom lasts two years in such places. It is esteemed one of the best sorts of fodder for most cattle, and is a great improvement to chalky hills, upon which it succeeds better than in any other soil, and will continue many years, provided there be a surface of six or eight inches upon the chalk. The best time for sowing the seed is the beginning or middle of April, according to the season, observing always to do it in dry weather, otherwise the seed will be apt to burst, and never come up. The seed being large, the common allowance is four bushels to an acre, but three are amply sufficient. If it were sown in rows, as directed for Lucerne, it would be a great improvement to the plants; for, when these have room enough, they branch out on every side, and become very strong; and by hoeing between them the natural grass may be kept down, which, if permitted to grow, will rob the sainfoin of its nourishment, and in time destroy it. Sainfoin is frequently sown with oats or barley, but this is a very bad method, for what is gained from the crop of corn, will be doubly lost in the sainfoin; and this generally holds true in most sorts of grass-seeds, for the corn growing over it, so weakens the crop beneath, that it scarcely recovers its strength in a year after. The ground in which the seed is sown should be well ploughed, and made very fine. If it be sown in drills, the drills should be hoed out to the distance of six or eight inches, when the ground is hoed to destroy the weeds. The first year, by no means feed the crop down; for, the crown of the roots being young and tender, cattle would eat it so low as entirely to destroy the

roots; and if large cattle were let in upon it, they would trample it down so much as to prevent its shooting again: the first year therefore it should be mowed, and this should be done when it is in flower. The sooner it is carried off the ground when cut, the better it will be for the plants. It does not require to be so often turned as other hay, for the stalks being large they will not lie so close in the cocks as to ferment; in catching-weather, therefore, the cocks may be made large, and, if they be turned and spread every other day, or once in three days, there will be little danger of its heating so as to receive damage; but if it be spread, and much exposed to rain and dew, the goodness of the hay will be exhausted. The crop will be fit to cut the first year towards the end of July, or at the beginning of August. After this is cleared off, the roots will soon shoot again, and by the end of September, provided the season be favourable, there will be a fine crop fit for feeding. Sheep will enrich the ground with their dung, and greatly strengthen the roots; but they should not be suffered to remain upon it longer than the middle of November the first year; and the succeeding years, when the crop is cut early, it should not be fed upon longer than the middle of September. The most common time of sowing saintfoin is in the spring; and it is even commonly reputed bad husbandry to sow it in the autumn, because the frost is apt to draw it out of the ground. It has, however, been sown with success in October along with wheat or rye, after winter tares. The crop was good, even the first season, though it happened to be a very dry one; whereas it was well known that saintfoin sown in the spring yields a very scanty crop the first year, even when assisted with manure. At either season it is commonly sown with corn; but it is still doubtful whether the crop of artificial grass may not be diminished in proportion as the crop of corn flourishes. Other seeds are sometimes sown with it, to give a crop the first year, as white clover, common red clover, and trefoil: of these the first is much the best. The quantity of seed usually sown is at least four bushels, and some sow five; though Mr. Miller is for sowing a less quantity. In drilling, two bushels are sufficient; but this is not a common practice with saintfoin. One of the best preparations for saintfoin, is to take two crops of turneps in succession, and then in the spring to sow four bushels of this seed with two bushels of barley. Coal-ashes are a good dress for saintfoin; and soot a still better, in the quantity of from ten to twenty bushels on an acre, laid on early in the spring. It is much infested with a kind of grass which botanists call *Bromus sterilis*, and farmers know by the name of Black-grass. The scythe slips over it: the seed ripens very early, and is difficult to separate from the saintfoin seed. It may easily be pulled up by hand. When the crop begins to fail, or the land is wanted for something else, a saintfoin lay may be broken up successfully for potatoes; for the red worm, which makes such ravages if corn be sowed without paring and burning, will not touch the potatoes. The hay made from plants saved for seed is no better fodder than chopped straw or chaff; and to have the hay in perfection, it should be cut before it begins to flower, when the juice abounds, and it will nourish cattle much more than when it stands to be in full flower. This plant is exceedingly wholesome for horses, and is esteemed one of the best sorts of food for cattle, especially in the spring, nor is there any danger attending the use of it, as there is in clover. It produces abundance of milk; and butter made of that milk is very good. Since it has been introduced into England, many dairy farms have been set up, where it was formerly impracticable: and if this plant and lucerne were properly cultivated to such an extent as they might be,

not only a much greater quantity of milch cows could be maintained, but a greater number of black cattle might be fattened, and more sheep and hogs, which would be a great improvement to many estates in hilly countries; for, by increasing the live-stock, there will be an addition of manure for dressing the land in proportion. Saintfoin is allowed on all hands to be an admirable improvement on lime-stone rocks and chalk downs; which, in order to be cultivated to the greatest advantage, should be in this course, with no more arable than is necessary for the change. Thus, if saintfoin last sixteen years, as it certainly will, if properly managed, then sixteen parts of the down should be saintfoin, and as many more parts as there are years necessary for tillage before the ground should be sown with it again: suppose this period to be five years, the portions would then be,

10, Saintfoin.

1, Saintfoin pared and burnt, and under Turneps.

1, Barley or Oats.

1, Clover.

1, Wheat.

1, Turneps.

1, Barley or Oats, and with this crop Saintfoin sown again.

16

Suppose each part to contain twenty-seven acres, then there would be two hundred and seventy acres of saintfoin; and so on. Saintfoin is also a vast improvement in thin, loose, dry, sandy loams, upon marl or chalk bottoms. Thin soils that wear out or tire of clover, are laid down to great advantage with it, will last twenty years, and pay the farmer as well as his best corn crops. If a flock of sheep be an object of primary importance, this plant will afford them plenty of dry food for winter in hard weather. An acre of indifferent land will yield two tons of saintfoin dry, and therefore twenty acres will serve a thousand sheep for a month, supposing a sheep eats three pounds of hay in a day, which is a large allowance. Now the expense of an acre of saintfoin, including fourteen shillings for rent, tithe, and poor, is about one pound; whereas that of an acre of turneps will be two pounds seven shillings. Eight acres and a half of turneps then balance twenty acres of saintfoin. Now, a thousand sheep will eat two acres and a half of turneps in a day; and therefore seventy-five acres will be required for a month, or, at the lowest calculation, twenty-four acres; the expense of which is fifty-six pounds eight shillings, to be set against twenty pounds, the expense of saintfoin. Some green food, however, should be joined with the hay, for milch ewes or cattle. Green borecole, the turnep-rooted cabbage, or the Swedish turnep, would answer this purpose; being hardy, and standing above the snow. One great advantage of this, in common with other artificial grasses, is, that even in a dry season from a ton to a ton and a half of hay may be obtained from an acre, when natural meadows unwatered will produce only half a ton. Modern authors affect to write *sainfoin*, as if the term meant *wholesome hay*; whereas it is called *saintfoin*, or holy hay, from a presumption of its superior excellence. Ignorant persons confound it with Cinquefoil, from the sound merely, for no two vegetables can be more different.

78. *Hedysarum Saxatile*; *Rocky Hedysarum*. Legumes one-seeded, furrowed, without prickles; wings of the corolla very short; scapes subradicate; stems under ground woody, above ground scarcely any; the spike resembles that of the foregoing species, but is whitish.—Native of Provence, the county of Nice, and Siberia. Perennial.

79. *Hedysarum Caput Galli*; *Cock's-Head Hedysarum*. Legumes one-seeded; teeth of the crest subulate; wings very

short; stem diffused; root white, annual; flower twice as long as the calix; banner ovate, retuse; keel shorter than the banner; wings very small, scarcely the length of the line, one-fourth of the length of the calix. It differs from the preceding species in its annual root, the minuteness of the wings in the corolla, and in the larger size of the legumes.—Native of France and Sicily.

80. *Hedysarum Crista Galli*; *Cock's-Comb Hedysarum*. Legumes one-seeded, prickly; divisions of the crest lanceolate, toothletted; root annual; petioles equal in length; the spine alone; the keel of the legumes are larger, lanceolate, serrate.—Native of the Levant.

81. *Hedysarum Crinitum*; *Crooked-podded Hedysarum*. Racemes long; legumes bent in; stem shrubby, five feet high, round, tomentose, with diffused branches; flower violet-coloured, in a close, round, straight, terminating spike, a foot long; bractes lanceolate, acuminate, ciliate; two-flowered; corolla banner roundish, entire, converging; wings shorter, oblong; keel crescent-shaped, of a length between the banner and wings.—Native of India, Cochin-china, and China.

82. *Hedysarum Comosum*. Leaves pinnate, lanceolate; racemes elongated, cylindric; stem shrubby; branches angular, villose; flowers crowded on very short pedicels. Jacquin describes it as a very handsome plant, with a perennial root; an upright round stem, a foot and a half high, leafy all over, closely hispid, with very minute white hairs; flowers at first red, but changing to blue, and soon falling.—Found by Kœnig in the East Indies, and by Issert on the coast of Guinea.

83. *Hedysarum Cornutum*; *Horned Hedysarum*. Leaflets linear; legumes one-seeded, even; stems shrubby; peduncles permanent, thorny; peduncles axillary, solitary, simple, mucronate, changing into round thorns, the length of the leaves, divaricating from the branch; flowers three or four, alternate, pedicelled, placed before the tip of the peduncle.—Native of the Levant.

84. *Hedysarum Incanum*; *Hoary-leaved Hedysarum*. Leaves without stipules, hoary underneath; stem erect; flowers in racemes, drooping, flesh-coloured. It has no stipules.—Native of Japan.

85. *Hedysarum Lineare*; *Linear-leaved Hedysarum*. Leaflets lanceolate-linear; spikes terminating; legumes straight, smooth and even; stem diffused, suffruticose, two feet high. The root is thought to be deobstruent, an emmenagogue, and to create an appetite.—Native of Cochin-china.

86. *Hedysarum Sericeum*. Leaves ternate; leaflets ovate, silky underneath; flowers in spikes, axillary and terminating; stem shrubby, six or seven feet high, dividing into several branches; flowers small, and of a bright purple colour; legumes flat, smooth, jointed, about an inch long.—Native of La Vera Cruz.

87. *Hedysarum Villosum*. Leaves ternate; stem diffused, villose; flowers in terminating spikes; calices very villose. This is an annual plant, seldom rising more than eight or nine inches high, sending out several branches from the root, which are diffused and hairy; spikes close and short; corolla purple.—Native of La Vera Cruz.

88. *Hedysarum Glabrum*. Leaves ternate; leaflets obcordate; stem panicled; legumes smooth, lunulate, compressed, standing oblique to the stem, one-seeded.—Native of Campeachy.

89. *Hedysarum Scandens*. Leaves ternate; leaflets obovate; stem twining; spike very long, bent back. It ascends to the height of ten or twelve feet. Flowers dark purple, sitting close to the stalk.—Native of La Vera Cruz.

90. *Hedysarum Pedunculatum*. Leaves ternate; the mid-

dle leaf on a longer petiole; racemes axillary, upright, very long; root perennial; stem annual, erect, about two feet high. The flowers are produced in long axillary spikes, growing erect; the lower part of the spike is but thinly set with flowers, but they are very closely disposed on the upper part; they are small, and of a bright yellow colour, sessile, and succeeded by jointed pods, straight on one side.—Native of South Carolina. For its propagation and culture, see the forty-third species.

Heistera; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, five-cleft, acute, small, permanent. *Corolla*: petals five, ovate, acute, concave, spreading. *Stamina*: filamenta ten, ovate, acute, flat, upright, alternately shorter; antheræ roundish. *Pistil*: germen roundish, flattened; style upright, short; stigma four-cleft, obtuse. *Pericarp*: drupe oblong, flattened at the tip, placed on a very large coloured calix. *Seed*: nut oval, obtuse. *Observe*: It is allied to *Laurus*. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Petals*: five; drupe with a very large coloured calix.—The only known species is,

1. *Heistera Coccinea*. This is an inelegant branching tree, twenty feet in height. Leaves oblong, quite entire, drawing to a sickle-shaped point, shining, on short petioles, alternate, half a foot in length; flowers small, axillary, with white corollas; calix in the flower small and green, in the fruit scarlet, with a very large spreading limb, and short very blunt roundish segments.—Native of Martinico, in closed woods near torrents, flowering in February and March, and fruiting in June. The French inhabitants call it *Bois Perdrix*, birds being very fond of the fruit.

Helenium; a genus of the class Syngenesia, order Superflua.—GENERIC CHARACTER. *Calix*: common simple, one-leaved, many-parted, spreading; leaflets about twenty, gradually drawing to a point. *Corolla*: compound, radiate; corollets hermaphrodite, numerous in the disk; females as many as there are parts of the calix in the ray. Proper of the hermaphrodites tubular, shorter than the calix, five-toothed; of the females ligulate, broader outwards, trifid at the tip, longer than the calix. *Stamina*: in the hermaphrodites: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: in the hermaphrodites: females; germen oblong; style filiform, length of the stamina; stigma bifid: in the females; germen oblong; style very short; stigma bifid. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites solitary, obovate, angular, crowned with a small five-toothed calicle: in the females, very like the others. *Receptacle*: naked, convex; the calicine chaffs only of the ray separating the florets. ESSENTIAL CHARACTER. *Calix*: simple, many-parted. *Corollets* of the ray, semi-trifid. *Down*, five-awned. *Receptacle*: naked, excepting the calicine chaffs in the ray.—The species are,

1. *Helenium Autumnale*; *Smooth Helenium*. Leaves very smooth. It rises to the height of six or seven feet in good ground; the roots when large send up a great number of stalks, which branch towards the top. The leaves sit close to the stalks, and from their base is extended a leafy border along the stalk, so as to form what was generally termed a winged stalk, but Linneus calls it a decurrent leaf; the upper part of the stalk divides, and from each division arises a naked peduncle about three inches long, sustaining one yellow flower, shaped like a sun-flower at the top, but much smaller, having long rays, which are jagged pretty deep into four or five segments; these appear in August, and there is a succession of flowers on the plants till the frost puts a stop to them.—Native of America, where its grows in great plenty in

the woods, and other shady places and moist grounds of Virginia and New England. This, as well as the next species, may be propagated by seeds, or by parting their roots; but the latter is generally practised in this country, because they seldom perfect seeds here, but if the seeds are procured from abroad, they should be sown in the beginning of March on a border of light earth: and if the seeds should not come up the first year, the ground should not be disturbed, because they often remain a whole year in the ground before the plants come up; in which case there is nothing more to be done, but to keep the ground clear from weeds, and wait until the plants rise. When they appear, if the season proves dry, they must be often watered, which will greatly forward their growth; and where the plants come up too close to each other, they should be thinned, and transplanted out into beds a foot asunder every way, being careful to shade them until they have taken root, as also to water them in dry weather. In autumn they may be transplanted where they are to remain, and the following summer they will produce their flowers, which will continue till the frost prevents them; and their roots will abide many years, and afford many offsets, by which they may be increased. The best season to transplant the old roots, and to part them for increase, is in the end of October, when their flowers are past, or the beginning of March, just before they begin to shoot; but if the spring should prove dry, they must be duly watered, otherwise they will not produce so many flowers the same year: these plants should not be removed oftener than every other year, if they be expected to flower strong: they delight in a soil rather moist than dry, provided it be not too strong, and does not hold the wet in winter; but when planted in a dry soil, they must be often and plentifully watered in dry weather, to make them produce plenty of flowers.

2. *Helenium Pubescens*; *Downy Helenium*. Leaves pubescent. This has the appearance of the preceding species, but the leaves are not three inches long, and are more than an inch broad in the middle, ending in acute points, and are sharply serrate on their edges. The flowers stand upon shorter peduncles, growing closer together, for the stalks of this do not branch half so much as those of the other: they both flower at the same season. It flowers in August and September.—Native of North America. For its propagation and culture, see the preceding species.

Helianthus; a genus of the class Syngenesia, order Polygamia Frustranea.—GENERIC CHARACTER. *Calix*: common imbricate, somewhat squarrose, expanded; scales oblong, broadish at the base, gaping every where at the tips. *Corolla*: compound radiate; corollets hermaphrodite, very numerous in the disk: females fewer, much longer in the ray. Proper of the hermaphrodites cylindric, shorter than the common calix, bellied at the base, orbiculate, depressed; border five-toothed, sharp, spreading: of the females ligular, lanceolate, quite entire, very long. *Stamina*: in the hermaphrodites, filamenta five, curved, inserted below the belly of the corollet, the length of the tube; antheræ cylindric, tubular. *Pistil*: in the hermaphrodites, germen oblong; style filiform, length of the corollet; stigma two-parted, reflex: in the females, germen very small; style and stigma none. *Pericarp*: none; calix unchanged. *Seeds*: in the hermaphrodites solitary, oblong, blunt, four-cornered, compressed at the opposite angles; the inner ones narrower, crowned with two lanceolate, acute, deciduous chaffs: in the females none. *Receptacle*: chaffy, large, flat; chaffs lanceolate, acute, two separating each seed, deciduous. ESSENTIAL CHARACTER. *Calix*: imbricate, somewhat squarrose.

Down: two-leaved. *Receptacle*: chaffy, flat.—The species are,

1. *Helianthus Annuus*; *Annual Sun-flower*. All the leaves cordate, three-nerved; peduncles thickening; flowers drooping; root annual; stem single or branched, from five or six to ten or fourteen feet in height, and in hot climates twenty or more; when vigorous, the size of a man's arm; flower single, nodding, a foot or more in diameter. The semiflorets, or ligulate floscules in the ray, are usually of a fine golden colour, and nearly an inch in breadth, ending in a point which is commonly bent back. The seeds are numerous, black, variegated, or white; and when these have quitted their cells, the receptacle looks like a honeycomb. The great size of the whole compound flower recommends it to the student for the examination of the floscules, which in the class Syngenesia are usually very small. The whole plant, and particularly the flower, exudes a thin, pellucid, odorous resin, resembling Venice turpentine. The seeds are excellent food for domestic poultry. The varieties are those with double flowers, and deep yellow, and sulphur-coloured. This flower becomes double by the change of tubular into ligular florets, like those in the ray, only smaller. Gerarde observes that it was called *Indian Sun-flower*, or *Flower of the Sun*, *Corona Solis*, and *Sol Indianus*, because it resembles the radiant beams of the sun. The report of its turning with the sun is a vulgar error. Gerarde says he could never observe it; and we have seen four flowers on the same stem pointing to the four cardinal points. It flowers from June to October.—Native of Mexico and Peru. This and the second species are easily propagated by seeds sown in March upon a bed of common earth; and when the plants come up, thin them where they are too close, and keep them clean from weeds; when the plants are grown six inches high, they may be taken up with balls of earth to their roots, and planted into the large borders of the pleasure garden, observing to water them till they have taken new root, after which they will require no other care but to keep them clear from weeds. In July the great flowers upon the tops of the stems will appear, amongst which the best and most double flowers of each kind should be preserved for seeds; for those which flower later upon the side branches are neither so fair, nor do they perfect their seeds so well, as those which are first in flower: when the flowers are quite faded, and the seeds are formed, the heads should be carefully guarded from the sparrows, which will otherwise devour most of the good seeds; and about the beginning of October, when the seeds are ripe, the heads, with a small part of the stem, should be cut off, and hung up for a month in a dry airy place until the seeds are perfectly dry and hard, when they may be easily rubbed out, and put into bags and papers, preserving them from vermin until the season for sowing them. The perennial sorts rarely produce seeds in England, but most of them increase very fast at their roots, especially the creeping-rooted kinds, which spread too far for small gardens. They are all very hardy, and will grow in almost any soil or situation; they are propagated by parting their roots into small heads, which in one year's time will increase greatly. The best season for this work is in the middle of October, soon after the flowers are past, or very early in the spring, that they may be well rooted before the droughts come on, otherwise their flowers will be few in number, and not near so fair, and by this means their roots will be weak; but if they be planted in October, it will supersede the trouble of watering them, as they will be securely rooted before the dry weather arrives, and will then only require to be carefully weeded.

2. *Helianthus Indicus*; *Dwarf Annual Sun-flower*. All

the leaves cordate, three-nerved; peduncles equal; calices leafy. This is suspected to be a variety of the foregoing; though it constantly preserves its distinction. It grows only from eighteen inches to three feet in height.—It is probably a native of Mexico or Peru. For its propagation and culture, see the preceding species.

3. *Helianthus Multiflorus*; *Perennial Sun-flower*. Lower leaves cordate, three-nerved; upper ones ovate; stem and peduncles scabrous. There is a constant succession of flowers from July to November. This, which is the most common in our English gardens, is the largest and most valuable flower, and is very proper furniture for large borders in great gardens, as also for bosquets of large growing plants, or to intermix in small quarters with shrubs, or in walks under trees, where few other trees will thrive; it is also a great ornament to gardens within the city, where it grows in defiance of the smoke better than most other plants; and, for its long continuance in flower, deserves a place in most gardens, for the sake of its flowers, for basons, &c. to adorn halls and chimneys, in a season when we are at a loss for other flowers. It begins flowering in July, and continues till October. There is a variety of this species with very double flowers, which is now become so common in the English gardens, as to have almost banished the single sort from hence.

4. *Helianthus Tuberosus*; *Tuberous-rooted Sun-flower*, or *Jerusalem Artichoke*. Leaves ovate-cordate, triple-nerved; stems several, rough, hairy, streaked, from ten or twelve to sixteen feet in height, the size of a child's arm; branches many, long from bottom to top; flowers terminating, small; florets in the ray twelve or thirteen. These seldom blow before October, and in some seasons they do not expand at all. The seeds never ripen here. Roots creeping, with many tubers clustered together, thirty, forty, or fifty, from one plant, measuring a peck, or in good soils half a bushel; they are like the common potatoe, red on the outside, and very irregular in their shape, the size of a man's fist at biggest. "Mr. John Goodyer received in 1617, two small roots no bigger than hens' eggs, from Mr. Franquevill of London; the one he planted, and the other he gave to a friend. The root he planted produced a sufficient number to supply all Hampshire." This note is dated the 17th of October, 1621; and Johnson observes, that his friend took it presently upon the first arrival into England. If this were the era of the first introduction of Jerusalem Artichoke, it seems surprising, even allowing for the facility with which it is increased, that so soon as the year 1629, or even earlier, it should have become so common in London, that even the most vulgar began to despise it; whereas when first received among us, it was, as Parkinson says, a dainty for a queen. By the latter expression, we are led to infer that it must have been known in the time of queen Elizabeth. Our ancestors boiled them tender, and after peeling ate them sliced and stewed with butter, wine, and spices. Thus, says Parkinson, they were a dish for a queen, being as pleasant as the bottom of an artichoke: but their too frequent use, owing to their being so plentiful and cheap, hath rather bred a loathing than a liking of them. They also baked them in pies, with marrow, dates, ginger, raisins, sack, &c. Notwithstanding what our old authors have above advanced, it is probable that this root was discontinued from a notion of its flatulent quality. The potatoe seems to be more nutritious and wholesome. It is not necessary therefore now to enforce the cultivation of Jerusalem Artichoke as a general article of food, but it certainly makes an agreeable variety at good tables. There is no better reason for the common English name, than that the root when boiled has the taste of an artichoke bottom: Parkinson there-

fore would have it called Potatoes of Canada, because the French brought them first from Canada into these parts. Not that Canada is their original country, for they are unquestionably the produce of a hot climate, being natives of Brazil.—These plants are propagated by planting the smaller roots, or the larger ones cut in pieces, observing to preserve a bud to each separate piece, either in the spring or autumn, allowing them a good distance, for their roots will greatly multiply; in the following autumn, when their stems decay, the roots may be taken up for use. They should be planted in some remote corner of the garden, for they are very unsightly while growing, their roots over-run every thing, and they cannot easily be destroyed. When desired for a crop, the sets should be planted in an open part of the kitchen garden, in rows three feet or more asunder, at least eighteen inches distant from each other, and four or five inches deep. The best time for this is the latter end of March. A light soil suits them best. Some persons cut the stalks half way down, at the end of July or the beginning of August; because they shade the ground too much, and from their great height are apt to be blown down. They may be taken up for present use in September, and the whole crop may be housed in October. If kept in sand, and in a dry place, they will continue the whole winter.

5. *Helianthus Decapetalus*; *Ten-petalled Sun-flower*. Stem smooth at bottom; leaves lanceolate, cordate, triple-nerved; ray of the flower ten-petalled; peduncles scabrous. This resembles the third species very much, but it differs in having the stem, which scarcely attains the height of a man, scabrous, but smooth at bottom; the corolla with not more than ten florets in the ray.—Native of Canada.

6. *Helianthus Frondosus*. Calix squarrose, waved, leafy; rays eight-petalled; leaves ovate; stem scabrous at bottom. This is allied to the foregoing species.—Native of Canada.

7. *Helianthus Strumosus*; *Carrot-rooted Sun-flower*. Root fusiform; stems several, nine or ten feet high, round, rough, somewhat hirsute, streaked, subdivided into numerous branches; leaves alternate, a hand long, an inch or more broad, acuminate, rough, dark green, slightly notched about the edge; flowers terminating in corymbs; petals pale yellow, ending in a bifid point; leaflets of the calix produced into long leaves; the roots are bitterish, aromatic, and not disagreeable: they are eaten by the Canadians, among whom this plant grows wild. It flowers from July to September.

8. *Helianthus Giganteus*; *Gigantic Sun-flower*. Leaves alternate, lanceolate, scabrous, ciliate at the base; stem stiff, scabrous, ten feet high; peduncles scabrous, hispid, usually about twenty florets in the ray, bifid at the end; the first two leaves of the branches are opposite, and have the appearance of stipules; the flowers nod more in the night than in the day. It flowers in September and October.—Native of Virginia and Canada.

9. *Helianthus Altissimus*; *Tall Sun-flower*. Leaves alternate, broadish lanceolate, scabrous; petioles ciliate; stem stiff, smooth. This strongly resembles the preceding species, but the leaflets of the calix are shorter, and not so copious. There are usually sixteen florets in the ray. It flowers in August and September.—Native of Pennsylvania.

10. *Helianthus Angustifolius*. Leaves alternate, linear; stem purplish, a foot and half in height; disk of the corolla brown; ray deep yellow, emarginate.—Native of Virginia.

11. *Helianthus Divaricatus*; *Rough-leaved Sun-flower*. Leaves opposite, sessile, ovate oblong, three-nerved; panicle dichotomous; stem scarcely the height of a man, extremely even at top, but with scattered rough hairs, purple, with a glaucous bloom; flowers in a panicle with trichotomous

branches, yellow, small, peduncled, with the middle peduncle simple; peduncles somewhat scabrous. It flowers from August to October.—Native of North America.

12. *Helianthus Atrorubens*; *Dark-red Sun-flower*. Leaves opposite, spatulate, crenate, triple-nerved, scabrous; calicine scales erect, the length of the disk; stem commonly single, about the size of a swan's quill at bottom, from eighteen inches to three feet and more in height, round, dusky purple, rough with abundance of whitish hairs; root-leaves flat, hairy, smaller than those on the stem, which are twisted and waved, especially towards the lower end, rough with frequent hairs, and on the lower ones particularly with small tubercles; flowering-branches divaricate; the disk of the flower dark red; floscules in the ray yellow, marked with a few lines, pointed and entire, sometimes in very old flowers divided into segments. It flowers in September and October, and continues two or three years.—Native of Carolina and Virginia.

13. *Helianthus Mollis*. Leaves ovate acuminate, very rough on the upper surface, and soft underneath. It flowers from July to October, and is found in the exsiccated swamps of Pennsylvania and Virginia.

Heliconia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: spathes common and partial alternate, distinct, with hermaphrodite flowers; perianth none. *Corolla*: petals three, oblong, channelled, erect, acute, equal. Nectary two-leaved: one leaflet nearly equal to the petals; the other very channelled, hooked, opposite. *Stamina*: filamenta five, (according to Adanson, six,) filiform. Antheræ long, erect. *Pistil*: germen inferior, oblong; style shorter than the stamina; stigma long, slender, curved with a terminating head. *Pericarp*: capsule oblong, truncate, three-sided, three-celled. *Seeds*: solitary, oblong. *Observe.* This genus is distinguished from Musæ by a tricocous capsule, and there is some doubt whether it ought not to be transferred to the class Hexandria. **ESSENTIAL CHARACTER.** *Spathes*. *Perianth*: none. *Corolla*: three-petalled. Nectary two-leaved. *Pericarp*: tricocous. *Seeds*: solitary; capsule fleshy, three-celled, according to Swartz.—The species are,

1. *Heliconia Bihai*; *Bastard or Wild Plantain*. Leaves and spadix radical; spathes distich, cordate; nectary ventricose, bifid at the tip. This is a very large herbaceous plant, from ten to twelve feet in height; petioles the length of the leaves or more, round, thick, channelled above; scape upright, the length of the petioles, round, thick, smooth; flowers in bundles concealed within each spathe; partial spathes membranaceous, whitish, the length of the flowers, which are distinct, sessile, pale or greenish yellow. *Corolla*: cohering at the base, unequal, curved and recurved, as it were two-lipped. The flowers have five perfect filamenta shooting from the bottom of the real flower-leaf, and one imperfect filamentum from the nectarium. The berries are small and succulent, and contain each three hard rugged seeds. This beautiful plant grows wild in most of the cooler mountains of Jamaica, and thrives very luxuriantly in every rich well-shaded gully among the woods. It flowers in the spring, and is a native of moist mountain-woods in the West Indies.

2. *Heliconia Psittacorum*. Leaves on the stem rounded at the base; spadix terminating, flexuose; spathes lanceolate; nectary lanceolate, concave, entire. This plant bears a great resemblance to Canna, and grows to the height of eight feet, with a simple smooth stem; flowers pedicelled, crowded, upright, an inch long, fulvous; on round peduncles, half an inch long. *Corolla* three-sided; the two upper petals erect, linear, acute, keeled, converging, glued to the nectary, the

uppermost only trifid; the lower petal embracing the upper petals and nectary at the base, a little wider, keeled, ventricose, brownish green at top.—Native of Jamaica in wet parts of mountain-woods, also of South America.

3. *Heliconia Hirsuta*. Leaves rounded at the base, simply nerved, very smooth; inflorescence hirsute; spadix flexuose; nectary lanceolate, adnate; stem very smooth; spathes alternate in two rows, lanceolate, awl-shaped, channelled, ascending, the lower ones larger, with a hispid keel; peduncles from nine to twelve in the axils of the spathes, upright, round, very hirsute, short, leafless, one-flowered; corolla curved, two-petalled; upper petal complicated, hispid, bifid at the tip; lower broader, complicated, hispid, oblong, with a brown mark on the inside at the top.—Found in South America by Mutis.

Helicteres; a genus classed by Linneus in Gynandria, order Decandria; by Schreber, in Decandria Monogynia; and by Swartz, in Monodelphia Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leafed, tubulous, half-ovate, obliquely spreading, unequally five-cleft, coriaceous. *Corolla*: petals five, oblong, equal in breadth, fixed to the receptacle, longer than the calix; claws long, with a tooth on each side at the base. Nectary of five petal-shaped, lanceolate, very small leaflets, covering the germen. *Stamina*: filamenta five, ten, or more, very short. Antheræ oblong, lateral. *Pistil*: receptacle filiform, very long, bowed back, bearing an ovate germen at the tip; style subulate, longer than the germen; stigma subquincifid. *Pericarp*: capsules five, often twisted spirally, one-celled. *Seeds*: very many, angular. *Observe.* In some species Jacquin and others have observed dodecandrous and polyandrous flowers, and straight capsules. One species has no corolla. **ESSENTIAL CHARACTER.** *Pentagynous*. *Calix*: one-leafed, oblique; petals five; nectary of five leaflets. *Capsule*: five, twisted.—The plants of this genus are propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are come up strong enough to remove, they should be each planted in a separate small pot, filled with light earth, and plunged into a moderate hot-bed of tan, observing to shade them from the sun until they have taken new root; then they should be treated in the same way as other tender plants from hot countries, raising the glasses every day in fine weather, that the plants may enjoy fresh air, without which they would be drawn up weak. In the summer the plants may remain under the frames, if there be sufficient height for them to grow; but in autumn they must be plunged into the tan-bed in the stove, where they should always remain, being careful to shift them into larger pots when they require it, and not to give them too much wet in the winter, but in summer they should have a large share of air in warm weather, and require to be often refreshed with water. These plants have often flowered in the Chelsea Garden during the second year of their production from seed, and have sometimes ripened seeds. They will live several years with proper management.—The species are,

1. *Helicteres Baruensis*; *Small-fruited Screw Tree*. Decandrous: leaves cordate, serrate; fruit twisted with straight tips. This is an upright tree, about twelve feet in height, branching but little; the younger branches, peduncles, and petioles, are tomentose; peduncles many-flowered, terminating thick; the flowers have no scent; petals whitish; seeds about fifty in each capsule, obovate, angular, smooth, of a brown chestnut colour. The bark of the trunk and principal branches being easily peeled off and very tough, is used instead of ropes.—Native of the island of Barú, in woods near the coast; and of the West Indies.

2. *Helicteres Isora*; *Great-fruited Screw Tree*. Decandrous; leaves cordate, serrate; the whole fruit twisted. Swartz describes it, "Leaves elliptic, subcordate; fruit subulate at the tip." A small upright tree, about twelve feet high, branching but little; peduncles many-flowered, terminating, glandular; petals white, obtuse, reflex. This curious shrub, as Browne calls it, is very frequent in the lower gravelly hills of Jamaica.

3. *Helicteres Hirsuta*. Decandrous: leaves cordate, serrate; fruit five-celled, straight, very hirsute; stem shrubby, six feet high, upright, round, hairy, with diffused branches; peduncles many-flowered, axillary; corolla dusky purple. In this and the fifth species the stamina are not gynandrous, but rather monodelphous; nor ought the pedicel supporting the germen to be looked upon as a receptacle, for it is entirely detached from the stamina.—Native of the woods of Cochinchina.

4. *Helicteres Undulata*. Decandrous: leaves lanceolate, waved; flowers in heaps; siliques five, stellate. This is a middling-sized tree, with spreading branches; flowers small, mostly terminating; calix none; corolla greenish red; siliques oblong, thick, scarlet, straight above, convex underneath; seeds few, ovate, smooth, brown, fleshy, adhering to each valve by their proper pedicels.—Native of Cochinchina, in woods.

5. *Helicteres Angustifolia*. Decandrous: leaves lanceolate, quite entire; fruit ovate, straight; stem shrubby, five feet high, upright, branched; flowers pale purple, on two-flowered axillary peduncles.—Native of China, in the neighbourhood of Canton.

6. *Helicteres Pentandra*. Pentandrous: leaves ovate, floral leaves coloured, dusky purple; calices hispid with branching bristles.—Native of Surinam.

7. *Helicteres Carthaginensis*. Polyandrous: leaves cordate, serrate; fruit oblong, straight: this is an upright tree, about twelve feet high; flowers extremely fetid, generally coming out with the leaves, but sometimes before them; calix brownish yellow; petals purple. It has so much the habit of the first sort, that it can hardly be distinguished from it, except in the flower and fruit.—Native of the woods of Carthage in New Spain, where it is found flowering in June and July.

8. *Helicteres Paniculata*. Polyandrous: leaves ovate, acute; flowers panicked; siliques five, stellate; this is a large tree with spreading branches; flowers in loose panicles, mostly terminating; calix none; corolla of a reddish colour, and spreading very much; siliques oblong, two-valved, red.—Native of the woods of Cochinchina.

9. *Helicteres Apetala*. Dodecandrous, apetalous: leaves five-lobed; siliques divaricate. This is an elegant tree, forty feet in height, with a large handsome head; the leaves are plaited, smooth above, subvillose beneath, upwards of a foot in diameter, and numerous; flowers also numerous, very fetid, dirty yellow with purple spots, without either petals or nectary, in large loose panicles at the ends of the twigs. It is apparent that the filaments are the continuation of the bark, or outer part of the receptacle, but that the germen springs from the pith of it.—Native of Carthage, in woods, flowering from May and June to September.

Heliocarpus; a genus of the class Dodecandria, order Dignia.—GENERIC CHARACTER. *Calix*: perianth four-leaved, coloured; leaflets linear, long, broadish, spreading, deciduous. *Corolla*: petals four, linear, much shorter than the calix, narrower. *Stamina*: filamenta sixteen, awl-shaped, almost the length of the calix. *Antheræ* twin, linear, incumbent. *Pistil*: germen roundish; styles two, simple, upright,

length of the stamina; stigmas acute, distant. *Pericarp*: capsule turbinate-ovate, peduncled, compressed, surrounded perpendicularly on both sides with rays pinnately branched, two-celled, two-valved, with the partition contrary. *Seeds*: solitary, subovate. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: four-petalled; styles simple. *Capsule*: two-celled, compressed, longitudinally radiated on both sides; according to Gærtner, superior, club-shaped, surrounded with filiform feathered rays. The only species known is,

1. *Heliocarpus Americana*; *American Heliocarpus*. It rises with a thick, soft, woody stalk, from fifteen to eighteen feet high, sending out several lateral branches towards the top; leaves heart-shaped, full of veins, serrate, ending in acute points, alternate, on oblique petioles three inches long. The flowers are produced at the ends of the shoots, in branching clusters, and are of a yellowish green colour. This plant is propagated by seeds, which must be sown upon a hot-bed in the spring; and when the plants are fit to remove, they should be each planted in a small pot, filled with light kitchen-garden earth, and plunged into a hot-bed, treating them in the same way as other tender plants which will not bear the open air in this country at any season of the year: while young, the plants require to be plunged into the tan-bed; but after they have acquired strength, they will thrive in the dry-stove. In winter they should have but little water, and must be kept warm; but in summer they should have plenty of fresh air in mild weather, and must be frequently refreshed with water. With this management the plants will flower the third year, and produce good seeds, and may be preserved by care for several years.

Heliophila; a genus of the class Tetradinamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets spreading, oblong, concave, membranaceous at the edge, deciduous, the two outer ones bladdery at the base. *Corolla*: four-petalled, cruciform; petals roundish, flat, sessile; nectaries two from the receptacle, bowed back towards the bladder of the calix. *Stamina*: filamenta six, awl-shaped, erect; the length of the calix, two opposite a little shorter; antheræ oblong, erect. *Pistil*: germen cylindrical; style shorter than the germen; stigma blunt. *Pericarp*: siliques columnar, somewhat torulose, mucronate, two-celled, two-valved. *Seeds*: several. **ESSENTIAL CHARACTER.** *Nectaries*: two, bowed back towards the bladder of the calix. The seeds of plants belonging to this genus may be sown in the spring on a south border; and when the plants come up, if they are thinned, and kept clean from weeds, it is all the culture they require.—The species are,

1. *Heliophila Integrifolia*; *Whole-leaved Heliophila*. Leaves lanceolate, undivided; stalk erect, four or five inches high, sending out two or three side-branches; the flowers grow in a loose terminating bunch, and have no scent; the corolla resembles that of Flax, or *Anagallis Monelli*: it is blue, and closes at night; the pods are nearly three inches long, taper, and contain a double row of flat seeds.—Native of the Cape of Good Hope.

2. *Heliophila Coronopifolia*; *Buck's-horn-leaved Heliophila*. Leaves linear, pinnatifid. This is a smooth shrubby plant.—Native of the Cape of Good Hope.

3. *Heliophila Amplexicaulis*. Leaves stem-clasping, entire, smooth; siliques necklace-shaped.—Found by Thunberg at the Cape of Good Hope.

4. *Heliophila Incana*; *Hoary Heliophila*. Leaves spatulate, quite entire, pubescent; siliques villose.—Found at the Cape of Good Hope, flowering in May and August.

5. *Heliophila Filiformis*; *Divaricated Heliophila*. Leaves subulate, filiform, smooth; siliques pendulous; branches

divaricate; stem half a foot high, herbaceous, rushy; racemes horizontal, on horizontal pedicels; petals spreading as the calix does, but nearly three times as large, pale, streaked; siliques awl-shaped, stiff, very smooth and even. It is annual, and flowers in July and August.—Native of the Cape of Good Hope.

6. *Heliophila Pusilla*; *Dwarf Heliophila*. Leaves linear; siliques necklace-shaped, upright. Annual, a span high, upright, branched.—Native of the Cape of Good Hope.

7. *Heliophila Flava*. Leaves linear; stems shrubby, rushy. It has the appearance of Broom, upright, sparingly branched, stiff; racemes terminating, long, simple; the flowers distant; petals obovate, the same size as the cabbage, yellow, veiny; the claws longer than the calix; germen ovate; it varies with red corollas. It is doubtful whether this be a natural species of this genus.—Native of the Cape of Good Hope.

8. *Heliophila Circæoides*. Leaves cordate; stem brittle, branched, herbaceous; the whole plant is succulent, weak, smooth; root fibrous, annual; petioles semicolumnar, channelled above, shorter than the leaf, spreading; flowers alternate, very remote, but towards the end nearer, peduncled; the flowering peduncles erect, a line in length, bearing one flower; fruit peduncles reflected; seeds three or four, roundish.—Native of the Cape of Good Hope.

9. *Heliophila Digitata*. Leaves palmate-pinnatifid, villose; pinnae linear. The stem thickens very much upwards, which gives this plant a very singular appearance.—Native of the Cape of Good Hope.

10. *Heliophila Pinnata*. Leaves trifid and pinnate; leaflets linear; siliques necklace-shaped, upright. This resembles the sixth species very much, but it has branched or pinnate leaves.—Native of the Cape of Good Hope.

Heliotrope. See *Heliotropium*.

Heliotropium; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, five-toothed, permanent. *Corolla*: monopetalous, salver-shaped; tube the length of the calix; border flat, half five-cleft, obtuse; clefts smaller, alternate, more acute between the larger ones; throat naked. *Stamina*: filamenta five, very short in the throat; antheræ small, covered; *Pistil*: germen four; style filiform, length of the stamina; stigma emarginate. *Pericarp*: none; calix erect, unchanged, cherishing the seeds in its bosom. *Seeds*: four, ovate, acuminate: according to Gærtner, nuts four, naked or corticate, not perforate. ESSENTIAL CHARACTER. *Corolla*: salver-shaped, five-cleft, with teeth interposed; throat closed with arches.—The species are,

1. *Heliotropium Peruvianum*; *Peruvian Turnsole* or *Heliotrope*. Leaves lanceolate-ovate; stem shrubby; spikes numerous, aggregate-corymbed. This rises with a shrubby stalk from two to three feet high, dividing into many small branches; leaves three inches long, and an inch and a half broad in the middle, hairy, greatly veined, and ash-coloured on their under side, on short foot-stalks; the flowers are produced at the ends of the branches in short reflex spikes, growing in clusters; the peduncles divide into two or three, and these again into smaller ones, each sustaining a spikelet of pale blue flowers, which have a strong sweet odour, of a very particular nature, somewhat resembling that of bitter almonds. It is a native of Peru. It flowers in England great part of the year; and those flowers which come out in summer are succeeded by ripe seeds in autumn. It may be propagated either by seeds or cuttings. The seeds may be sown upon a moderate hot-bed in the spring; when the plants are fit to remove, transplant them into small pots filled with light earth, plunge them into a hot-bed, and shade them till they have

taken new root; then inure them by degrees to the air, into which remove them in summer, placing them in a sheltered situation: in autumn, house them in a good green-house, where they will flower during great part of the winter. If the cuttings be put into pots filled with light earth, during any of the summer months, and plunged into a moderate hot-bed, they will take root freely; but these do not make so good plants as those taken from seed. Mr. Curtis remarks that "a stove is most congenial to this plant in winter, when it must be carefully defended from the frost, so fatal to most of the natives of Peru." In hot weather it must be well watered.

2. *Heliotropium Indicum*; *Indian Turnsole* or *Heliotrope*. Leaves cordate-ovate, acute, somewhat scabrous; spikes solitary; fruits bifid; stem herbaceous, a foot and half or two feet high, round, scabrous, hirsute, subdivided; flowers sessile, pointing one way, approximating in a double row, small, blue; tube very long, cylindric, not globular, as in the others; border scarcely half five-cleft; segments equal, blunt; throat five-rayed, orange-coloured, closed; germina in connate pairs. It is annual or biennial, flowers in July and August, and ripens seed in September and October. The variety, which Mr. Miller makes a distinct species, is a smaller plant, seldom above two feet high; the leaves are an inch and half long, and about half an inch broad; the spikes of flowers are very slender, and not more than two inches long; the flowers are small, and of a light blue colour. This, together with the third and ninth species, require their seed to be sown on a hot-bed in the spring, and when the plants are fit to remove, transplant them on another hot-bed, to bring them forward, treating them in the same way as the Balsamine, and other tender annual plants. They should be taken up in June with balls of earth, and replanted in the borders of the flower-garden, where they will flower, and in warm seasons produce ripe seeds.

3. *Heliotropium Parviflorum*; *Small-flowered Turnsole* or *Heliotrope*. Leaves ovate, wrinkled, scabrous, opposite and alternate. This is nearly allied to the foregoing. Stem erect, pubescent, a foot high; most of the leaves opposite, except those in the middle of the stem, which are alternate, petioled, lucid, acute; peduncles opposite to the leaves, or from the divisions of the stem, longer than the leaves, erect, each having two recurved imbricate spikes; corolla minute, pervious, white with a yellow base. It is an annual plant, flowers in July and August.—Native of the West Indies. For its propagation and culture, see the preceding species.

4. *Heliotropium Inundatum*. Leaves oblong, obtuse, hirsute; spikes in fours, erect; stem shrubby.—Native of the Caribbee Islands.

5. *Heliotropium Europæum*; *European Turnsole* or *Heliotrope*. Leaves ovate, quite entire, tomentose, wrinkled; spikes conjugate. This rises about seven or eight inches high, dividing into two or three branches, at the ends of which the flowers are produced in double spikes, joined at the bottom, about an inch long, turning backward; flowers white, appearing in June and July. There is a variety with large sweet flowers. This and the seventh species are annuals, which succeed better from the seeds scattered in autumn, or are sown at that season, than in the spring, when they seldom appear in the same season; but if the seeds be suffered to shed, these plants will maintain themselves without any other culture, but keeping them clean from weeds, and thinning them where too close.

6. *Heliotropium Malabaricum*. Leaves ovate, plaited, strigose, quite entire; spikes almost solitary.—Native of Malabar.

7. *Heliotropium Supinum*; *Trailing Turnsole* or *Helio-*

trope. Leaves ovate, quite entire, tomentose, plaited; spikes solitary. This is smaller than the common sort, with more slender branches, somewhat lanuginous and prostrate; the root small and annual; flowers white.—Native of the Cape of Good Hope; flowering in June and July. For its propagation and culture, see the fifth species.

8. *Heliotropium Fruticosum*. Leaves linear-lanceolate, hairy; spikes solitary, sessile; stem shrubby, two feet high, very much branched; branches stiff, scabrous, and ash-coloured; spikes always single, and not much bent, small and slender; flowers terminating on short pedicels, pointing one way, on short, axillary, hispid peduncles; corolla white; border five-cornered; throat closed, pale, having five rays from the centre to the angles of the border.—Native of the West Indies, near the sea-shore. This and the seventeenth and eighteenth species are propagated by seeds, but the difficulty of getting them fresh from America, and the uncertainty of their growing unless they are sown abroad, and brought over in earth, has made them scarce in Europe.

9. *Heliotropium Curassavicum*; *Glaucous Turnsole* or *Heliotrope*. Leaves lanceolate-linear, smooth, without veins; spikes conjugate; root annual; stem round, very smooth, with a glaucous gloom on it; spikes in pairs, on a common peduncle, and recurved; corolla white, with a yellow base and an open throat; the fruit is an ovate, globular berry, containing four nuts, drying up as it grows ripe, and divisible into four parts: it flowers in June and July. See the second species.—Native of the West Indies.

10. *Heliotropium Orientale*. Leaves linear, smooth, without veins; spikes conjugate. It is a small, procumbent, creeping plant. Annual.—Native of Asia.

11. *Heliotropium Guaphaloides*. Leaves linear, obtuse, tomentose; peduncles dichotomous; flowers of the spikes in fours; stem frutescent. It is an upright shrubby plant, commonly about two feet high, and sometimes, but rarely, rising to the height of six feet; branches round, little divided, the older ones blackish, the younger scarred at bottom where leaves have grown, all together forming a convex, white, handsome head, visible far off at sea; flowers small, with the calices of all so connected, that no one can be taken out without tearing the rest.—Native of Cuba, Jamaica, Barbadoes, and St. Eustatia, in all of which it is found upon the coast. It is propagated by seeds, which must be procured from the places where it naturally grows, for it never produces any in Europe; these seeds should be sown in a tub of earth in the country, for when the dried seeds come over, they seldom grow; and if they do, it is not before the second year: so that if the seeds be sown as soon as ripe in a tub of earth, when they arrive in England, the tub should be plunged into a hot-bed of tanner's bark, which will bring up the plants; and when they are fit to remove, they should be each planted in a separate small pot filled with soil composed of sand and light undunged earth, with a little lime-rubbish well mixed together, then plunged into a hot-bed of tanner's bark, and shaded until they have taken new root; after which they must be treated in the same manner as other tender exotic plants, always keeping them in the tan-bed in the stove, giving them but little water during the winter.

12. *Heliotropium Scabrum*. Leaves lanceolate, strigose; stem branched, diffused; flowers heaped; root simple, fusiform; flowers terminating, small, white, fenced with leaves.—Sent by Kœnig from the East Indies.

13. *Heliotropium Marifolium*. Leaves lanceolate, hispid; stems procumbent, somewhat shrubby; spikes simple, alternate; root woody; spikes copious without order, not compact, with bractes of the same shape with the leaves; flowers white,

hirsute on the outside, as also are the calices.—Native of the East Indies.

14. *Heliotropium Coromandelianum*. Leaves obovate, villose, entire; spikes simple and conjugate; seeds dotted; root simple, fusiform; stems erect and prostrate, hispid.—Native of the East Indies, and also of Arabia.

15. *Heliotropium Capitatum*. Leaves oblong-ovate, quite entire, smooth, hoary underneath; flowers in axillary heads, stem arborescent. It rises with a shrubby stalk six or seven feet high: the young branches are closely covered with a white down, and the leaves on them are very hoary and entire, but those on the older branches are greener, and some of them are notched on their edges. At each joint of the stalks appear two short branches opposite, with small hoary leaves placed opposite; these when bruised emit a strong odour very disagreeable to some persons, and by others reckoned very pleasant. They rarely flower in England. Mr. Miller cultivated them for forty years, and only saw them once in flower. The flowers are white, collected in roundish heads, which turn backward and sit close to the branches; the leaves continue all the year. Both this and the next species are too tender to endure the winter of this country in the open air. They must be protected from the frost in a green-house, and may be ranged with myrtles and other hardy green-house plants, where they may have a large share of air in mild weather, and be treated in the same way: they are easily propagated by cuttings during any of the summer months. If the cuttings be planted in a shady border, and duly supplied with water, they will take root in five or six weeks, and may then be potted, and placed in a shady situation till they have taken new root, after which they may be treated as the old plants.

16. *Heliotropium Canariense*. Leaves ovate, crenate, opposite; flowers in dichotomous axillary heads; stem arborescent, three or four feet high. The leaves when bruised emit an agreeable odour, for which it is by some persons much esteemed. The gardeners have given this plant the title of *Madame de Maintenon*, but on what account we do not know.—Native of Canada. For its propagation and culture, see the preceding species.

17. *Heliotropium Procumbens*. Stem procumbent; leaves ovate, tomentose, quite entire; spikes solitary, terminating. It is an annual plant, with trailing stalks six or seven inches long. The flowers are produced at the ends of the branches, in single short spikes, which are reflexed; they are small and white, making little appearance.—Native of Carthage in New Spain. For its propagation and culture, see the eighth species.

18. *Heliotropium Americanum*. Leaves oblong, ovate, tomentose; spikes conjugate, terminating; stem shrubby. This rises with a shrubby stalk, three feet high, dividing into slender branches, which are closely garnished with leaves, placed without order. The flowers are produced at the ends of the branches in double spikes, which are slender, short, and straight, not recurved as the other species; flowers small and white; plant perennial.—Native of Vera La Cruz, where it was found growing in great plenty. For its propagation &c. see the eighth species.

19. *Heliotropium Tetrandrum*. Leaves ovate, lanceolate, smooth, opposite; spikes heaped, terminating; stem herbaceous, annual, one foot high, somewhat erect, diffused, whitish, obtusely four-cornered, with purple joints; flowers red, in long close spikes.—Native of the gardens of Cochin-china.

20. *Heliotropium Undulatum*. Leaves lanceolate, hispid, rolled back at the edge, waved; spikes conjugate; corollas villose; stem procumbent; branches a span long and more; calix hairy, five-cleft with linear blunt segments; corolla

hairy on the outside, longer than the calix.—Native of Arabia.

21. *Heliotropium Lineatum*. Leaves elliptic, petioled; villose, rolled back at the edge, flat; spikes conjugate; stem procumbent; branches slender, a span long, villose, tomentose above; corolla smooth, longer than the calix; tube widening at the top. Distinguished from the preceding by the form and hairiness of the leaves, with the edge not at all waved, by the presence of bractes, by the smoothness of the corolla, and by the stigma being quite entire.—Native of Arabia.

22. *Heliotropium Ternatum*. Leaves in threes, and alternate lanceolate, hoary underneath; spikes terminating, conjugate; branches round, hoary, with small hairs pressed close; corolla white.—Native of the West Indies.

23. *Heliotropium Pinnatum*. Leaves pinnate; stem erect, herbaceous, simple, only branching a little at the base, a foot high, the size of a goose-quill, villose. Peduncles axillary and terminating; flowers crowded.—Found in the straits of Magellan.

24. *Heliotropium Amplexicaule*. Leaves lanceolate, obtuse, half stem-clasping; spikes branching; stem shrubby; branches hairy; from the axils there are rudiments of branchlets; peduncle terminating, hairy, twice or thrice dichotomous at top; tube of the corolla twice as long as the calix, with fewer villose hairs scattered over it.—Found in Brazil.

Hellebore. See *Helleborus*.

Hellebore White. See *Veratrum*.

Helleborine. See *Arethusa Divaricata*, and *Serapias*.

Helleborus. A genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: none, unless the corolla, which in some species is permanent, be so called. *Corolla*: petals five, roundish, blunt, large; nectaries several, very short, placed in a ring, one-leaved, tubular, narrower at bottom; mouth two-lipped, upright, emarginate, the inner lip shorter. *Stamina*: filamenta numerous, subulate; antheræ compressed narrower at bottom, upright; *Pistil*: germina about six, compressed; styles subulate; stigmas thickish; (Gærtner says, pistilla five or more, permanent.) *Pericarp*: capsules (leguminous beaked, according to Gærtner) compressed, two-keeled, the lower keel shorter, the upper convex, gaping; seeds several, round, fixed to the suture. *Observe*, The first species drops its petals, the other sorts retain them, and they become green: the number of pistils varies much. **ESSENTIAL CHARACTER.** *Calix*: none. *Petals*: five, or more (or *Calix*: five-leaved, *Corolla*: none.) *Nectary*: two-lipped, tubular; *Capsule*: many-seeded.—The species are.

1. *Helleborus Hyemalis*; *Winter Hellebore* or *Aconite*. Flowers solitary, sitting in the upper leaf; root tuberous, transverse, with many dependent fibres, putting up several naked stems or scapes, simple, smooth, round, from an inch or two to four inches in height, terminated by a single leaf, spreading out horizontally in a circle, divided into five parts almost to the base, and the parts simple or divided into two, three, or four lobes. In the bosom of this sits one large, upright, yellow flower; the petals ovate, marked with lines, converging, a little deciduous, usually six in number, or from six to eight; pistils six, or from four to six; and stamina about thirty. This, like all the other hellebores, is a powerful medicine, and requires great caution in the application: see the third and fifth species. Gerarde calls it *Winter's Wolfsbane*, and *Small Yellow Wolfsbane*; and it is now generally known by the name of *Winter Aconite*.—Native of mountainous situations in Austria, Silesia, Switzerland; also of Lombardy, and other parts of Italy. This flowers very early in the spring, which renders it worthy of a place in all curious gardens, especially as it requires

but little room: it is propagated by offsets, which the roots send out in plenty; these roots may be taken up and transplanted any time after their leaves decay, which is generally from the beginning of June till October; when they will begin to put out new fibres; but as the roots are small, and nearly of the colour of the ground, so, if care is not taken to search them, many of the roots will be left in the ground; they should be planted in small clusters, otherwise they will not make a good appearance; for single flowers of this small kind, when scattered about the borders, can scarcely be seen at a distance; but when planted in bunches alternately with *Snowdrops*, will have a good effect, as they flower at the same time, and are much of a size. This plant flowers so early, that it is liable to be cut off by severe frosts.

2. *Helleborus Ranunculinus*; *Ranunculus-leaved Hellebore*. Flowers solitary, peduncled; leaves digitate, multifid, gashed; stem a hand in height, upright, round, smooth, leafy at the top, sustaining one or two flowers, which are axillary, solitary, peduncled, upright, and yellow. It is very nearly related to the preceding species, but handsomer. Tournefort imported it from Cappadocia.

3. *Helleborus Niger*; *Black Hellebore*, or *Christmas Rose*. Stem almost naked, with one or two flowers; leaves pedate; roots transverse, externally rough and knotted, with many dependent fibres, and some large roots striking down; corolla very large, generally white at first, but frequently with a tint of red, growing deeper with age, and finally becoming green. It derives the name of *Black Hellebore* from the colour of the root; and of *Christmas Rose*, from the time of flowering and the colour of the corolla. Culpeper confounds this plant with the fifth species, but his account will apply equally well to both. He says it is not safe to give it raw, and that if any harm arise from taking it in that state, the common cure is to take goat's milk; and where that cannot be obtained, such milk as can be gotten. The roots, adds he, are very effectual against all melancholy diseases, especially such as are of long standing, as quartan agues and madness; it helps the falling sickness, the leprosy, both the yellow and black jaundice, the gout, sciatica, and convulsions: but unfortunately this renowned herbarist has forgotten to inform us, what part of the plant is to be taken for each disease, together with the quantity of the dose, and the manner of application; so that we cannot avail ourselves of his experience and skill. Not so in what follows: The root, used as a *pessary*, provokes the terms exceedingly; and if a beast be troubled with a cough, or have taken any poison, bore a hole through his ear, and put a piece of the root in it, this will help him in twenty-four hours! From these ridiculous whimsies we gladly revert, to detail the acknowledged virtues of the plant. Although many writers consider the root a perfectly innocent and safe medicine, yet as we find several examples of its poisonous effects, it should always be employed with great caution. It seems to have been principally owing to its purgative quality, that the ancients esteemed this root such a powerful remedy in maniacal disorders; because they supposed it evacuated the black bile, from which those diseases were then thought to proceed: but, though evacuations be often found necessary, in various cases of alienation of mind, yet as they can be produced with more certainty and safety by other medicines, this catholicon of antiquity seems now almost entirely abandoned. It is however still used in small doses of six or eight grains, for attenuating viscid humours, promoting the uterine and urinary discharges, and opening inveterate obstructions of the remoter glands; it often proves a powerful emmenagogue in plethoric habits, where steel is considered as improper: it is also used in dropsies, and in some cutaneous diseases. The

roots of the plant, says Dr. Hill, are the only parts to be used in medicine. These are of a bitter pungent taste, and, if chewed for a few minutes, leave a sensation of numbness on the tongue, which continues for a considerable time; given in substance, in doses of ten or fifteen grains, it purges roughly, and, to such as are of robust habits, may prove serviceable in dropsical complaints; but cloves, cardamoms, or some other warm spice, should always be joined with it, to correct its ill qualities, and render the use of it more safe; taken in smaller doses, it promotes urine and perspiration, and is very much extolled for its singular efficacy in obstructions and suppressions of the menses: it is likewise useful in all hysteric, nervous, and hypochondriacal complaints; and was at one time esteemed almost a specific for madness. There is a tincture of it kept in the shops, which is by far the best preparation for internal use: thirty or forty drops of this is a dose; but in order to be productive of any remarkable effects, the use of it must be persevered in for a considerable length of time. It flowers from December to March, and is a native of Italy, Germany, Austria, Idria, and Silesia, in mountainous situations. Like most alpine plants, it loves a pure air, a moderately moist situation, and an unmanured soil. It will not thrive in the neighbourhood of London. The flowers being liable to be injured by frost, must be covered during the winter with hand-glasses, or preserved in pots in a common hot-bed frame, without which they cannot retain their beauty long. It is propagated by parting the roots in autumn, for the seeds seldom ripen well in England.

4. *Helleborus Viridis*; *Green Hellebore*. Stem bifid; branches leafy, two-flowered; leaves digitate; peduncles axillary, an inch long, round, supporting two (sometimes only one) nodding green flowers.—Native of France, Italy, Austria, Carniola, Silesia, and Switzerland. Ray, in his history, gives no hint of this or the next species being natives of England; and seems, in his Synopsis, to think that they are not aboriginals here: Hobart, however, speaks of this species as growing wild abundantly in Stoken Church woods, and many other rocky and hilly situations: it is found near Cambridge, near Leeds in Yorkshire, near Arundel Castle in Sussex, in various parts of Kent, Oxfordshire, Northamptonshire, where Parkinson mentions his having seen it in the woods in Worcestershire and Hampshire; it is found also among bushes in the woods and pastures of Dunglass Glen, Scotland, flowering in March and April. If the seeds of this and of the next species be permitted to scatter, or are sown soon after they become ripe, the plants will come up early in the following spring, and when they have obtained sufficient strength, may be transplanted into woods or wilderness quarters, where they will thrive and flower very well in the shade, and make a good appearance when few other plants are in flower.

5. *Helleborus Fœtidus*; *Stinking Hellebore*, or *Bear's-foot*. Stem many-flowered, leafy; leaves pedate; root small, but bent with a prodigious number of slender, dark-coloured fibres: at the divisions of the branches are oval lanceolate stem-clasping stipules deeply bifid at the extremity; at the base of each peduncle, an oval lanceolate entire bract: both these are frequently tinged with purple; flowers almost globular, pendent on peduncles, forming a sort of umbel. This species is always green, whereas the preceding species dies down to the root every year. It is often called Black Hellebore, and is frequently used as an anthelmintic; the powder of the dried leaves being the preparation principally made use of, and this in doses of about fifteen grains for children, the decoction of about a drachm of the green leaves being

considered as equal to fifteen grains of the dry ones: it is usually repeated on two, and sometimes three, successive mornings; and seldom fails to bring away worms, if there be any in the intestinal tube. A decoction of the roots is a violent purge, and should be very sparingly used. Country people cut them into pieces, they insert these pieces into holes made in the ears and dewlaps of cattle, which produces a suppuration and discharge that proves serviceable in many disorders, and probably is the practice alluded to by Culpeper, mentioned under the third species, but the object and effect of which, he has left entirely unexplained. The powder of the roots or leaves strewed on issues, greatly promotes the discharge, and consequently renders them more efficacious. It is, however, necessary to keep the root in your own garden, for that offered for sale is of another kind, and a rough and dangerous medicine.

6. *Helleborus Lividus*; *Livid, Purple, or Great Three-flowered Black Hellebore*. Stem many-flowered; leaves ternate; flowering from January to May. The leaves are broader with a smoother surface, and the stalks rise higher, than any of our common sorts.—Native place unknown. It has been usual to treat this species as a green-house plant, or at least to shelter it under a frame in the winter: probably it is hardier than we suppose. It is propagated by parting its roots in autumn, and by seeds; but few of the latter ripen in general, nor do the roots make much increase: this is the real cause of its present scarcity. As it flowers in February, and is a singular plant, it well deserves to be admitted into every collection.

7. *Helleborus Trifolius*; *Small Three-leaved Hellebore*. Scape one-flowered; leaves ternate; stem leafless; flower minute, resembling that of the Parnassia, and white, and sometimes yellow.—It is a native of Denmark, Siberia, Hudson's Bay, and of Canada, where it is so abundant in the woods as to cover the ground in many parts: it commonly chooses mossy places that are not very wet; Woodsorrel and Alpine-Circæa are its companions. It is universally called *Tissavoyanne jaune* by the Canadian French. The leaves and stalks are used by the Indians, for giving a fine yellow colour to several kinds of work, which they make of skins; and the French use it to die wool yellow. It flowers in June and July.

Helmet Flower. See *Aconitum*.

Helonias; a genus of the class Hexandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals six, oblong, equal, deciduous; *Stamina*: filamenta, six; subulate, a little longer than the corolla. *Antheræ* incumbent; *Pistil*: germen roundish, three-cornered; styles three, short, reflex; stigmas blunt. *Pericarp*: capsule roundish, three-celled. *Seeds*: roundish. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: six-petalled. *Capsule*: three-celled. The plants of this genus may be increased by offsets, taken from the roots in autumn; or by seeds, which should be sown soon as ripe: they prefer a light fresh soil, and are hardy enough to thrive in the open air. They must not be removed oftener than once in three or four years; and they are as long in coming to flower from the seed.—The species are,

1. *Helonias Bulbata*; *Spear-leaved Helonias*. Leaves lanceolate, nerved; root perennial, composed of many thick fleshy fibres; the stalk is terminated by a close obtuse spike of dark red flowers, some of which are barren.—Native of moist shady places near Philadelphia, where it is called *Star-grass* by the natives; and is of an acrid aromatic flavour. It flowers in April and May.

2. *Helonias Asphodeloides*; *Grass-leaved Helonias*. Stem-leaves setaceous; stem extremely simple, two feet high; flowers white, in a simple terminating raceme, on peduncles

longer than the flowers. It very much resembles an Asphodel, but has three recurved styles.—Native of Pennsylvania and Virginia. It flowers in May and June: for its propagation and culture, see the preceding species.

3. *Helonias Tenax*. Flowers white; antheræ yellow. It approaches very near to the second species, but its flowers are three times larger. Found on high lands, near the rocky mountains of North America.

Helvella; a genus of Fungus.—GENERIC CHARACTER. Turbinate, with both upper and under surface smooth.—The species are.

1. *Helvella Mitra*; Stipitated.—Native of the woods of Great Britain.

2. *Helvella Pineti*. Without any stalk: also a native of the woods of Great Britain.

3. *Helvella Plana*. Stemless.—Native of Jamaica.

4. *Helvella Versicolor*. Stemless.—Native of the West Indies.

5. *Helvella Tremellina*. Stemless.—Native of Cuba, and of Jamaica.

6. *Helvella Atrata*. Stemless.—Native of Jamaica.

7. *Helvella Amara*. Stipitated, parasitical; esculent, and wholesome.—Found in the woods of Great Britain.

Hemerocallis. A genus of the class Hexandria: order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: six-parted, bell funnel-form; tube short; border equal, spreading, more reflex at top. *Stamina*: filamenta six, subulate, the length of the corolla, declining, upper ones shorter; antheræ oblong, incumbent, rising. *Pistil*: germen roundish, furrowed, superior; style filiform, the length and situation of the stamina; stigma obtusely three-cornered, rising. *Pericarp*: capsule ovate, three-lobed, three-cornered, three-celled, three-valved. *Seeds*: very many, roundish. ESSENTIAL CHARACTER. *Corolla*: bell-shaped; the tube cylindrical. *Stamina*: declining.—The species are,

1. *Hemerocallis Flava*. *Yellow Day Lily*. Leaves linear, subulate, keeled; corollas yellow. It has strong fibrous roots, to which hang knobs or tubers, like those of the Asphodel, from which come out leaves two feet long, with a rigid midrib, the two sides drawing inward, so as to form a sort of gutter on the upper side: the flower-stalks rise two feet and a half high, having two or three longitudinal furrows; these are naked, and at the top divide into three or four short peduncles, each sustaining one pretty large yellow flower, shaped like a lily, having but one petal, with a short tube, spreading open at the brim, where it is divided into six parts: they have an agreeable scent, from which some have given this plant the title of *Yellow Tuberosa*. It flowers in June, and the seeds ripen in August. There is a variety with smaller roots, which is also a native of Siberia, Hungary, Dalmatia, Istria, and has found its way into Switzerland and Silesia. This and the next species are easily propagated by offsets, which the roots send out in plenty; they may be taken off in autumn, (that being the best season for transplanting the roots,) and planted in any situation, for they are extremely hardy, and will require no culture but weeding, and room sufficient to spread their roots. This species may also be propagated by seeds, which, if sown in autumn, the plants will come up in the following spring, and these will flower in two years; but if the seeds are not sown till spring, the plants will not come up till the year after. In a moist soil and shady situation they thrive better than in dry ground.

2. *Hemerocallis Fulva*. *Copper-coloured Day Lily*. Leaves linear, subulate, keeled; corollas tawny or copper coloured. This is a much larger plant than the first, and the roots spread and increase much more; the flower-stalks are as

thick as a man's finger, and rise nearly four feet high; they are naked, without joints, and branching at the top, where there are several copper-coloured flowers, shaped like those of the red lily, and as large. The stamina are longer than those of the preceding species, and their summits are charged with a copper-coloured farina, which sheds on being touched. The flowers appear in July and August, and only last each one day, though there is a succession on the same plant for a fortnight or three weeks.—Native place of growth uncertain. In Japan it varies with a double flower, and in China and Cochin-china the inhabitants boil the flowers, both fresh and dry, commonly with their meat. It is a very unsuitable plant for small gardens, and best adapted for plantations. For its propagation and culture, see the first species.

3. *Hemerocallis Lancifolia*. Leaves lanceolate, seven-nerved; scape round, jointed, upright, smooth, longer than the leaves; flowers at the top of the scape in racemes dropping; peduncle round, smooth, half an inch in length; corolla white; tube furrowed, half an inch long.—Native of Japan, where it is frequently kept in gardens and houses for its elegance. Flowers in August and September.

4. *Hemerocallis Japonica*. Leaves ovate, waved, many-nerved; petioles winged, membranaceous, a hand in length or rather more.—Native of Japan.

5. *Hemerocallis Cordata*. Leaves heart-shaped, veined; stem round, upright, smooth, a foot high or more; flowers terminating, alternate, upright. Gærtner doubts whether this be a genuine species of *Hemerocallis*, since it differs so much in the fruit.—Native of Japan, where it is frequently cultivated.

Hemimeris; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, five-parted almost to the base, much shorter than the corolla; parts ovate, unequal, permanent. *Corolla*: monopetalous, wheel-shaped, ringent; tube very short (scarcely any,) intruded, white; upper lip cloven with a kind of bag at the base composed of little nectareous pits; lower concave, blunt. *Stamina*: filamenta two or four, filiform, inserted into the base of the lower lip, bent round: antheræ very small, heart-form, cohering, yellow. *Pistil*: germen superior, sharp, smooth; style thread-form, of the same length and in the same situation with the stamina; stigma simple, sharpish. *Pericarp*: capsule ovate, sharp, twin, gibbous at the base on one side, two-celled, two-valved. *Seeds*: very many, smooth. *Observe*. Allied to *Antirrhinum*, but differing in the form of the corolla.—ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: wheel-form; upper lip cloven, with a nectareous bag at the base. The species are,

1. *Hemimeris Sabulosa*. Diandrous: leaves opposite, pinnatifid; stem prostrate.—Native of the Cape of Good Hope.

2. *Hemimeris Montana*. Diandrous: leaves opposite, ovate, serrate; stem upright.—Native of the Cape of Good Hope. Probably a mere variety of the preceding.

3. *Hemimeris Diffusa*. Didynamous: leaves alternate and opposite, pinnatifid; stem patulous.—Native of the Cape of Good Hope.

Hemionitis, or *Mule Fern*; a genus of the class Cryptogamia, order Filices or Ferns.—GENERIC CHARACTER. Capsules digested into lines meeting together, either intersecting each other or branched.—The species are,

1. *Hemionitis Lanceolata*. Fronds lanceolate, quite entire; leaves plain and simple, seldom exceeding sixteen or eighteen inches in length, when most luxuriant; they grow in tufts from a strong fibrous root. This plant is commonly found on the trunks of trees, in the cooler and more shady inland woods of Jamaica. Neither this nor any of its genus is often

propagated in gardens. They must all be procured from the country where they naturally grow; planted in pots filled with loamy undunged earth, and placed in the stove: in summer they must be frequently watered, but they require little in winter. They require abundance of free air in summer.

2. *Hemionitis Lineata*. Frond lanceolate-linear; lines of fructifications nearly parallel, longitudinal.—Native of Jamaica. See the first species.

3. *Hemionitis Parasitica*. Fronds ovate, acuminate; shoots chaffy, creeping; leaves about two inches long, and one and a half over where broadest. Creeping on trees in the cooler inland woods of Jamaica. See the first species.

4. *Hemionitis Palmata*. Fronds palmate, hirsute; roots many, fibrous, black; stalks black, cornered, about six inches high, covered with ferruginous hair; the whole frond is like the leaf of a creeping *Ranunculus*.—Found between Savannah and Two-mile Wood in Jamaica, and also in Martinico. See the first species.

5. *Hemionitis Japonica*. Fronds bipinnate; pinnae lanceolate, entire. The fructifications are in trichotomous lines, over the whole lower surface.—Native of Japan. See the first species.

6. *Hemionitis Reticulata*. Fronds lanceolate-sickled, quite entire; veins netted.—Native of the Society Islands. See the first species.

7. *Hemionitis Esculenta*. Frond pinnate; pinnae alternate, lanceolate, crenate, slightly eared at the base. This species is a foot and half high or more; stipe smooth, grooved; roots esculent. See the first species.

8. *Hemionitis Prolifera*. Frond pinnate, decumbent; pinnae lanceolate, crenate; axils proliferous.—Native place unknown. See the first species.

Hemlock Common. See *Conium*.

Hemlock Water. See *Cicuta*.

Hemp. See *Cannabis Sativa*.

Hemp Agrimony. See *Eupatorium*.

Hemp Agrimony Water. See *Bidens*.

Hemp Bastard. See *Datisca*.

Hemp Virginia. See *Acnida*.

Henbane. See *Hyoscyamus*.

Heracleum; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: umbel universal manifold, very large, partial flat; involucre universal many-leaved, caducous, partial halved on the outside; leaflets three to seven, linear, lanceolate, the exterior ones larger; perianth obscure. *Corolla*: universal, not uniform, radiate; floscules all generally fertile. Proper: of the disk equal, five-petalled; petals bent in and hooked, emarginate; of the ray unequal, five-petalled; the outer ones larger and more bifid, oblong, hooked. *Stamina*: filamenta five, longer than the corollets; antheræ small. *Pistil*: germen subovate, inferior; styles two, approximating, short; stigmas simple. *Pericarp*: none; fruit elliptic, compressed, emarginate, striated in the middle on both sides, margined. *Seeds*: two, ovate, leafy, and compressed. *Observe*. In some species the radiate female flowers are fertile; the male ones of the disk are abortive, being destitute of stigmas. The first and second species are hermaphrodite throughout, and sometimes the involucre is entirely wanting. The second species has uniform flowers. ESSENTIAL CHARACTER. *Involucre*: caducous. *Corolla*: difform, inflex-emarginate; fruit elliptic, emarginate, compressed, striated, margined.—To propagate the plants of this genus, sow their seeds in autumn; in the spring, when the plants are up, hoe the ground, cutting up the weeds and thinning the plants, as directed for Parsneps.—The species are,

1. *Heracleum Sphondylium*; *Common Cow-Parsnep*. Leaflets pinnatifid, even; flowers radiate; root biennial, thick, yellowish without, white within, running deep into the ground, sweet to the taste, with some acrimony; stem two, three, and four feet high, round, furrowed, rough with white hairs, hollow within, branched from the bottom. The universal umbel is flat, and has ten, twelve, or more rays; the partial umbel has upwards of thirty; florets white, greenish white, or purplish; they have a horned appearance before they expand, particularly the outer ones, which are four times the size of the inner petals; the central flowers are frequently abortive; the seeds have a strong smell, somewhat like that of a bug; but are accounted diuretic and stomachic. Linneus says that the plant is used in Scania for the dysentery; and Gmelin informs us that the inhabitants of Kamtschatka, about the beginning of July, collect the footstalks of the radical leaves, and after peeling off the rind, which is very acrid, dry them separately in the sun, and then tying them in bundles, lay them up carefully in bags placed in the shade, where they become covered with a yellow saccharine efflorescence, tasting like liquorice, which being shaken off, is eaten as a great delicacy. The Russians distil an ardent spirit from the stalks thus prepared, by first fermenting them in water with the great bilberries; and the spirit thus produced is said to be more agreeable to the taste than spirits made from corn. The leaves are a favourite food with rabbits and swine: horses are said not to like them, but kine, sheep, and goats are partial to them. The Germans call this plant *Heilkrant*, *Barenklau*; the Dutch, *Heilkruid*, *Beerenklaauw*; the Danes, *Biorneklov*; the Swedes, *Biornloka*; the French, *la Berce*; the Italians, *Sfondilio*; the Spaniards, *Essondilio*, the Portuguese, *Canabraz*; and the Russians, *Putschki*, *Slatkaja trawa*; the old English writers call it *Cow-Parsnep*, *Meadow Parsnep*, and *Madnep*. It is called *Hogweed* in Norfolk; and in various parts of England the dry stalks are named *Keexes* or *Keeksies*, in common with those of some other plants.

2. *Heracleum Angustifolium*; *Narrow-leaved Cow-Parsnep*. Leaves crosswise, pinnate; leaflets linear; corollas flosculose. It is a mere variety of the foregoing. Hudson remarks, that the distinction of the flosculose and radiate corolla is very uncertain. It grows plentifully near Berkhamstead in Hertfordshire, near the place where Ray found it; and where both sorts may be seen growing from the same root. There are other varieties also, not worth enumerating.

3. *Heracleum Sibericum*; *Siberian Cow-Parsnep*. Leaves pinnate; leaflets in fives, the middle ones sessile; corollets uniform; root biennial; stem deeply furrowed, hispid; flowers flosculose, by no means radiate; petals green, bent in, not at all emarginate; universal involucre none. The Kamtschadales extract a kind of spirit from this species, which is called *Raka*.—Native of Siberia.

4. *Heracleum Panaces*; *Palmated Cow-Parsnep*. Leaves pinnate; leaflets in fives, the middle ones sessile; flowers radiate; root biennial; stem much taller than the common sort, attaining the height of six feet, hirsute, round, slightly angular, branched; flowers large, radiate, greenish or yellowish white. Gerarde calls it *Hercules All-Heal*.—Native of Italy, Silesia, and Siberia.

5. *Heracleum Austriacum*; *Austrian Cow-Parsnep*. Leaves pinnate, wrinkled, and scabrous on both sides; flowers sub-radiate; root knotty with circles round it and a few fibres; stem from a foot to two feet in height, slightly angular, striated, solitary, smooth, soft, with a white pile only towards the top, scarcely branched. It flowers in July and August.—Native of Austria, Carniola, and Silesia.

6. *Heracleum Alpinum*; *Alpine Cow-Parsnep*. Leaves

simple; flowers radiate; stem from eighteen inches to three feet high, round, smooth, jointed; corollas white, radiate, smaller than in the rest.—Native of the Swiss Alps, Provence, and Silesia.

7. *Heracleum Lanatum*. Petiole of the leaves woolly and very villose; seeds orbiculate; flowers white.—Found in shady woods on rich moist soil, in Canada and Pennsylvania, flowering in June and July.

Herb Bennet. See *Geum*.

Herb Christopher. See *Actæa*.

Herb Paris. See *Paris*.

Herb Robert. See *Geranium*.

Heritiera; a genus of the class Monœcia, order Monadelphia, or, according to Schreber, order Syngenesia.—GENERIC CHARACTER. *Male flowers*: smaller than the females. *Calix*: perianth one-leaved, bell-shaped, five-toothed. *Corolla*: none. *Stamina*: in the centre of the calix, columnar, conic-subulate, below the tip surrounded by antheræ from five to ten in number, minute, united into a cylinder. *Female Flowers*: in the same panicle with the males. *Calix*: as in the males. *Corolla*: none. *Stamina*: filamenta none; antheræ ten, inserted into the receptacle at the base of the germina, two between each, twin, minute, perhaps barren. *Pistil*: germina five, semiovate, compressed, smooth; styles conical, short, in flowering-time cohering at the tip; stigmas club-shaped. *Pericarp*: drupes juiceless, spreading very much, oval, flatish above, convex underneath, keeled and winged, one-celled. *Seeds*: solitary, subglobular, large. *Observe*. This character is formed from dried specimens, compared with Kœnig's manuscript descriptions, taken from living plants upon the spot. **ESSENTIAL CHARACTER.** *Calix*: five-toothed. *Corolla*: none. *Male. Antheræ*: ten, without filamenta. *Female. Germina*: five; drupes with one subglobular seed.—The only species yet discovered is,

1. *Heritiera Littoralis*; *Looking-glass Plant*. A tree with alternate, oval-oblong, obtuse, perennial, thick, veined, smooth, quite entire, petioled leaves.—Found in Ceylon and Pulo Condore, and generally a native of the East India islands.

Hermannia; a genus of the class Monadelphia, order Pentandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, roundish, inflated; the little clefts bent in, permanent. *Corolla*: pentapetalous, spiral against the sun; claws the length of the calix, with a little membrane on each side converging into a cowed nectareous tube; border spreading, broadish, blunt. *Stamina*: filamenta five, broadish, very slightly coalescing at bottom into one body; antheræ upright, acuminate, converging. *Pistil*: germen roundish, five-sided, five-cornered; styles five, filiform, approximating, subulate, longer than the stamina; stigma simple. *Pericarp*: capsule roundish, five-sided, five-celled, gaping at the top. *Seeds*: very many, small; according to Gærtner, kidney-form. **ESSENTIAL CHARACTER.** *Styles*: five; capsule five-celled. *Petals*: semitubular at the base, oblique.—The plants of this genus are all propagated by planting cuttings of them during any of the summer months, in a bed of fresh earth, observing to water and shade them until they are well rooted, which will be in about six weeks after planting: then take them up with a ball of earth to their roots, and plant them into pots filled with light fresh earth, placing them in a shady situation until they have taken fresh root; after which they may be exposed to the open air with myrtles and geraniums, until the middle or end of October; when they must be removed into the green-house, observing to place them in the coolest part of the house, where they may have as much free air as possible; for if they are too much drawn in the house, they will appear faint and sickly, and seldom produce many flowers; whereas

when they are only preserved from the frost, and have a great share of free air, they will appear strong and healthy, and produce large quantities of flowers in April and May, during which season they make a very handsome appearance in the green-house: they must also be frequently watered, and will require to be new-potted at least twice every year, in May and September, without which their roots would be so matted as to retard their growth. These plants, except the ninth and twenty-first species, seldom produce good seeds in England, which is probably owing to their having been long propagated from cuttings only, for they are generally fruitful when raised from seeds.—The species are,

1. *Hermannia Althæifolia*; *Marshmallow-leaved Hermannia*. Leaves ovate, crenate, plaited, tomentose, flowery; calices bell-shaped, angular; stipules oblong, leafy. This seldom rises more than two feet and a half high; the stem is not very woody, and the branches are soft and tender.—Native of the Cape of Good Hope.

2. *Hermannia Plicata*; *Plaited-leaved Hermannia*. Leaves cordate-ovate, toothletted, plaited, tomentose, flowering; calices oblong-ovate, subcylindrical. It flowers in November and December.—Native of the Cape of Good Hope.

3. *Hermannia Candicans*; *White Hermannia*. Leaves ovate, subcordate, blunt, tomentose, flowering; calices patulous, somewhat angular; stipules subulate. The whole plant is covered with a very white down.—Native of the Cape of Good Hope.

4. *Hermannia Salvifolia*. Leaves ovate, entire, wrinkled, tomentose, hispid; flowers drooping.—Native of the Cape of Good Hope; found there by Thunberg.

5. *Hermannia Biserrata*. Leaves ovate, lanceolate, unequal, serrate, smooth; flowers drooping.—Found by Thunberg at the Cape of Good Hope.

6. *Hermannia Trifurca*. Leaves lanceolate, entire, three-toothed; flowers in racemes, pointing one way; petals blue.—Native of the Cape of Good Hope.

7. *Hermannia Alnifolia*; *Alder-leaved Hermannia*. Leaves wedge-shaped, marked with lines, plaited, crenate-emarginate. It rises with a shrubby stalk six or eight feet high, dividing into many erect irregular branches, covered with a brown bark. The flowers are produced in short spikes on the upper part of the branches; they are small, and of a pale yellow colour, appear in April and May, and ripen into seed in August.—Native of the Cape of Good Hope.

8. *Hermannia Odorata*; *Sweet-scented Hermannia*. Leaves oblong-lanceolate, tomentose, wrinkled underneath, the lower one truncate and toothletted; calices pitcher-shaped and angular. It flowers most part of the year.—Native of the Cape of Good Hope.

9. *Hermannia Hyssopifolia*; *Hyssop-leaved Hermannia*. Leaves lanceolate, blunt, serrate. It rises with a shrubby stalk to the height of seven or eight feet, sending out many woody lateral branches, growing very erect. The flowers come out in small bunches from the side of the stalk: they are of a pale straw colour, appear in May and June, and are frequently followed by seeds, which ripen in the latter part of August.—Native of the Cape of Good Hope.

10. *Hermannia Lavendulifolia*; *Lavender-leaved Hermannia*. Leaves lanceolate, blunt, quite entire. This has shrubby branching stalks, which are very bushy, but seldom rise more than a foot and a half high, and are very slender. The flowers come out singly from the side of the stalk, are small and yellow, and continue most part of the summer.—Native of the Cape of Good Hope.

11. *Hermannia Denudata*; *Smooth Hermannia*. Leaves lanceolate, sharp, even, serrate at top; stems upright, round,

smoothish, stiff; flowers from the top, from the alternate oppositions of the stipules, or from a two-flowered peduncle, peduncled; corolla yellow. It flowers from May to July.—Native of the Cape of Good Hope.

12. *Hermannia Glabrata*. Leaves lanceolate, sharp; gash-serrate, smooth; flowers drooping.—Found by Thunberg at the Cape of Good Hope.

13. *Hermannia Ciliaris*. Leaves lanceolate, sharp, entire and serrate, ciliate.—Native of the Cape of Good Hope.

14. *Hermannia Linifolia*. Leaves linear; peduncles one-flowered.—Native of the Cape of Good Hope.

15. *Hermannia Filifolia*. Leaves linear, three-sided, quite entire.—Native of the Cape of Good Hope.

16. *Hermannia Trifoliata*. Leaves ternate, sessile, plaited retuse, tomentose. Stem creeping; branches narrow; flowers pendulous.—Native of the Cape of Good Hope.

17. *Hermannia Triphylla*. Leaves ternate, petioled, flat, obovate; stems herbaceous; stipules small; petals the length of the leaves: the whole plant has hairs thinly scattered over it.—Native of the Cape of Good Hope.

18. *Hermannia Grossularifolia*; *Gooseberry-leaved Hermannia*. Leaves lanceolate, pinnatifid. This is of lower stature than the seventh species, but sends out a greater number of branches, which spread wide on every side. The flowers are produced in short close spikes at the end of every shoot, so that the whole shrub seems covered with them; they are of a bright yellow, and appear towards the end of April, but are not succeeded by seeds in England.—Native of the Cape of Good Hope.

19. *Hermannia Pulchella*. Leaves lanceolate, pinnatifid; pinnae entire and gashed; stem upright, even.—Found by Thunberg, at the Cape of Good Hope.

20. *Hermannia Diffusa*. Leaves lanceolate, pinnatifid; pinnae entire and toothed; peduncles capillary, two-flowered; stem procumbent.—Native of the Cape of Good Hope.

21. *Hermannia Hirsuta*. Leaves simple and ternate, hirsute, sessile. It rises with a shrubby hairy stalk about two feet high, sending out many side-branches which grow very erect; the flowers are produced towards the end of the branches; they are large, and of a deep yellow colour, with large swollen hairy calices. It continues flowering most part of the summer.—Native of the Cape of Good Hope.

Hermas. A genus of the class Polygamia, order Monœcia.—GENERIC CHARACTER. *Hermaphrodite*, umbel terminating; *Calix*: umbel universal, many-rayed, hemispheric. *Partial*: many-rayed; central ray flower-bearing, the rest without any floret: involucre universal, many-leaved, lanceolate, short, permanent. *Partial*: of one or two leaves, lanceolate, the length of the partial umbel; proper perianth obscure, five-toothed. *Corolla*: universal flosculous; of the proper, petals five, oblong, ovate, upright, flat, entire, equal. *Stamina*: filamenta five, filiform, shorter than the petals; antheræ barren, oblong. *Pistil*: germen inferior, compressed, larger than the corolla; styles two, filiform, upright, longer than the corolla; stigmas obtuse. *Pericarp*: none. Fruit orbicular, emarginate at the base, gaping at the angles; seeds two, cordate, orbicular, compressed, flat, margined, marked with a single longitudinal elevated streak. *Male umbels lateral, later, of the same plant*. *Calix*: umbel universal, as in the hermaphrodite. *Partial*: many-rayed, the rays all flower-bearing. *Involucre*: as in the hermaphrodites. *Stamina*: filamenta five, filiform, length of the corollet. *Antheræ*: pollen-bearing, oval, nearly twin. ESSENTIAL CHARACTER. *Hermaphrodite*: Umbel: terminating. *Involucre*: universal and partial; umbellets with truncate rays, the central one floriferous. *Petals*: five. *Stamina*: five, barren. *Seeds*:

in pairs, suborbiculate. *Male umbels*: lateral, with universal and partial involucre, umbellets many-flowered. *Petals*: five. *Stamina*: five, fertile. For the mode of propagating and cultivating the plants of this genus, see *Bupleurum*.—The species are,

1. *Hermas Depauperata*. Stem shrubby; leaves oblong, embracing, toothed, villose underneath. This is an umbelled plant, with the leaves radical, subpetioled, cordate, coriaceous, white, tomentose underneath; umbels at the ends of the stem and branches, peduncled, compound.—Native of the Cape of Good Hope.

2. *Hermas Gigantea*. Leaves lanceolate, ovate, lanuginose above, underneath tomentose, entire; stem four feet high, with a small leaf or two towards the lower part; the axils villose. The wool scraped from the leaves is used at the Cape of Good Hope (where it is a native) for tinder, like that obtained from the *Artemisia* in China and Japan.

3. *Hermas Capitata*. Stem tomentose; leaves subcordate, serrate; umbels capitate; heads three, alternate, peduncled, composed of florets, scarce visibly pedicelled, as in the flowers of the class Syngenesia.—Native of the Cape of Good Hope.

4. *Hermas Quinquedentata*. Stem smooth; leaves ovate, five-toothed, tomentose underneath; umbel solitary. This is very distinguishable from the rest, by its small leaves with five fine deep serratures.—Native of the Cape of Good Hope.

5. *Hermas Ciliata*. Stem smooth; leaves ovate, ciliate, tomentose underneath; umbel several.—Discovered by Thunberg at the Cape of Good Hope.

Hernandia; a genus of the class Monœcia, order Triandria.—GENERIC CHARACTER. *Male flowers*: by pairs, lateral in each umbel. *Calix*: involucre partial, four-leaved, three-flowered; leaflets ovate, obtuse, spreading very much; perianth none. *Corolla*: petals six, subovate, spreading, the three inner ones narrower. *Nectary*: six glands, round-headed, placed round the filamenta. *Stamina*: filamenta three, shorter than the petals, inserted into the receptacle; antheræ upright, oblong, large. *Female flower*: intermediate. *Calix*: involucre common with the males; perianth inferior, one-leaved, bell-shaped, entire, permanent; according to Gærtner, inflated. *Corolla*: petals six or eight, of which four are interior and narrower, all sitting on the germen; nectary glands four, obovate, alternate with the interior petals. *Pistil*: germen roundish; style filiform; stigma oblique, somewhat funnel-shaped, large. *Pericarp*: drupe dry, ovate, eight-furrowed, one-celled, inclosed in a very large, inflated, roundish, fleshy-coloured perianth, with the mouth entire. *Seed-nut*: globular, slightly depressed. *Observe*. Corolla monopetalous, in the male six-parted, in the female eight-cleft. ESSENTIAL CHARACTER. *Male*. *Calix*: three-parted. *Corolla*: three-petalled. *Female Calix*: truncate, quite entire. *Corolla*: six-petalled; drupe hollow, with an open mouth, and a moveable nucleus. *Nut*: superior, clothed with the calix, inflated; seed globular and bony, according to Gærtner.—The species are,

1. *Hernandia Sonora*; *Whistling Hernandia*. Leaves peltate. This is an upright lofty tree, with an elegant head; the flowers are of a pale yellow colour in paniced racemes; the calices of the fruit are yellow. It is very common in the West Indies in gullies near rills of water; the English there call it *Jack-in-a-box*, and the French *Myrobolan*. Dr. Patrick Browne says it is common in Barbadoes and Montserrat, where it grows to a considerable size; but that he had not seen it in Jamaica, though he had been credibly informed that it is frequent in the parish of Portland. He attributes the whistling noise which the motion of these plants produces to the cups that sustain and partly envelope the nuts, which, he adds, are very large, and, as they move in the wind, produce

sound enough to alarm unwary travellers. The seeds are very oily. Sow the seeds of this curious plant in a hot-bed in the spring; when the plants are two inches high, transplant each into a separate pot, filled with fresh rich earth, and plunged into the hot-bed again, observing to water and shade them until they have taken root; after which admit air to them by raising the glasses, in proportion to the warmth of the air, or the heat of the bed; and water them frequently. As the plants advance, remove them into larger pots, being careful not to break the roots, and to preserve a good ball of earth to them: if their leaves hang, screen them from the sun until they have taken new root. Shift them in July, that they may be well rooted before the cold approaches. Keep them constantly in the bark-stove; in winter give them a moderate share of heat, and in summer plenty of air when the weather is hot. With this management, the plants will grow to the height of sixteen feet or more, and the leaves being very large, will make a beautiful appearance in the stove.

2. *Hernandia Ovigera*; *Egg-fruited Hernandia*. Leaves ovate, petioled at the base.—Native of the East Indies; not yet introduced into European culture.

Herniaria; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted, sharp, spreading, coloured within, permanent. *Corolla*: none. *Stamina*: filamenta five, subulate, minute within the parts of the calix; antheræ simple; filamenta other five, alternate with the parts of the calix, barren. *Pistil*: germen ovate; style scarcely any; stigmas two, acuminate, the length of the style. *Pericarp*: capsule small, in the bottom of the calix covered, scarcely gaping. *Seed*: solitary, ovate-acuminate, shining. *Observe*. The third species drops a fifth part of the number in the calix and stamina, and the fourth differs a little in the character from its congeners. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: none. *Stamina*: five, barren, besides the fertile ones. *Capsule*: one-seeded.—The species are,

1. *Herniaria Glabra*; *Smooth Rupture-wort*. Herbaceous and smooth. It is chiefly distinguished from the following species by the smoothness of its habit; the stalks are trailing and many, forming a little tuft, the length of the finger, or at most six inches round, with many alternate branches; leaves ovate or ovate-lanceolate, something like those of wild thyme, opposite, sessile or subsessile, smooth, bright green; flowers axillary, glomerate, sessile, six or eight together at the joints of the stem and branches. This plant was formerly in some reputation, not only for curing ruptures, but the stone, gravel, and dropsy; it was also given in disorders of the eyes, but has now fallen into utter disuse. Withering and Pollich, however, still aver that it increases the secretions by the kidneys, and that the juice will remove specks from the eyes. It is saltish and astringent, and, according to Krockner, is agreeable to sheep. Mr. Miller remarks, that the herbwomen used commonly to bring the Parsley Breakstone, or *Alphanes Arvensis*, to market instead of this plant. It is common in the sandy soils of Switzerland, Sweden, Denmark, Germany, France, Italy, Carniola; with us in England, at the Lizard Point, Cornwall, flowering in July. Both this and the second sort, if suffered to shed their seed, will propagate better than if sown.

2. *Herniaria Hirsuta*; *Hairy Rupture-wort*. Herbaceous and hairy. The general opinion concerning this plant is, that it is a mere variety of the former; but whether specifically distinct or not, it is easily distinguished by the whole plant being hairy. It flowers in July and August, and is a native of Germany, Switzerland, Italy, Carniola, and has been found with us close to Colney Hatch, near Barnet. See the first species.

3. *Herniaria Fruticosa*; *Shrubby Rupture-wort*. Stems shrubby; flowers four-cleft. This has stalks trailing on the ground, with small hairy leaves like the second sort; the flowers also bear a great resemblance to that. It is perennial, and may be propagated by cuttings.

4. *Herniaria Lenticulata*. Stems somewhat shrubby; leaves ovate-oblong, hairy. In habit, this plant resembles the first sort, but is very soft. It has a very small five-parted corolla.—Native of the East Indies and Cape of Good Hope; said to have established itself in France and Spain.

Hesperis; a genus of the class Tetradynamia, order Siliquosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets lanceolate-linear, from parallel converging at top, incumbent at bottom, gaping, deciduous: of these, two opposite ones are gibbous at the base. *Corolla*: four-petalled, cruciform; petals oblong, the length of the calix, a little bent back obliquely, contrary to the sun's apparent motion, ending in attenuated claws the length of the calix. *Stamina*: filamenta six, subulate, the length of the tube, two of them shorter by half than the others; antheræ linear, upright, reflex at the tip; an acuminate honied gland between each shorter stamen and the germen, and surrounding the germen. *Pistil*: germen the length of the calix, prismatic, four-cornered; style none; stigma two-parted, placed on the inside, oblong, upright, forked at the base, converging at the tip, withering. *Pericarp*: silique long, pressed flat, stiff, and straight, two-celled, two-valved; the valves of the same length with the partition; seeds very many, ovate, compressed. *Observe*: in the sixth species the siliques are knotted and three-cusped. ESSENTIAL CHARACTER. *Petals*: bent obliquely; a gland within the shorter stamina; silique stiff; stigma with a forked base and converging tip. *Calix*: closed.—The species are,

1. *Hesperis Tristis*; *Night-smelling Rocket*. Stem hispid, branched, spreading. The leaves of this sort are much larger than those of the Garden Rocket, and of a paler green, the stalks are closely set with bristly hairs; the flowers grow in loose panicles at the top of the stalk, and appear about the same time as the Garden Rocket. It is much cultivated on the continent, for the great fragrantcy of its flowers in the evening. The German ladies place pots of it in their apartments, whence it has obtained the name of *Dame's Violet*. It is propagated by seeds in the same way as the Garden Rocket; which see. It is not quite so hardy, being very subject to rot in winter, especially in a moist soil or in rich land; it should be planted therefore in a dry poor soil and a warm situation. If some plants be set in pots, and placed under a common frame in winter, it will be sure to preserve them.

2. *Hesperis Matronalis*; *Garden Rocket*. Stem simple, upright; leaves ovate-lanceolate, toothletted; petals emarginate, with a point. This grows naturally in Italy. It rises with an upright stalk a foot and half high, with spear-shaped leaves which sit close to the stalk, and are slightly indented on their edges, ending in acute points; the flowers are produced in a loose thyse on the top of the stalks; the petals are roundish, and indented at the points, of a deep purple colour, and smell very sweet, especially in the evening, or in cloudy weather. The Garden Rocket with purple flowers was formerly more plentiful in England, and has been neglected merely because the flowers are single and make but little show, although their scent is so grateful that they deserve a place in every good garden. There are several varieties of this plant, one with white flowers, but having less scent; another with double white flowers, mentioned by Johnson in 1633; and a third called the *Siberian Rocket*, which is nearly the same in all its parts with the common Garden Rocket. Mr. Ray

observed the wild single sort between Salerno and Naples. The Siberian Rocket is very fragrant. These young biennial plants should be raised every year, to supply the place of those which decay; if the seeds are permitted to scatter, the plants will come up without trouble in the spring; and if the seeds are sown, the best season for it is in the autumn; because those sown in the spring often fail when the season proves dry, or will remain a long time in the ground before they vegetate. It will thrive better in a loamy undunged soil than in rich land.

3. *Hesperis Inodora*; *Unsavoury* or *Scentless Rocket*. Stem simple, upright; leaves subhastate, toothed, blunt. It rises with an upright stalk nearly two feet high; the flowers grow in loose spikes on the top of the stalks; in some they are white, in others purple, and sometimes both colours striped in the same flower; but having no odour, they are not so deserving of being introduced into gardens. From this species, the double white and purple rockets have been accidentally obtained: they are much esteemed for the beauty of their flowers; and if they also possessed the agreeable odour of the Garden Rocket, they would be some of the best furniture for the borders of the flower-garden, for though scentless, many highly esteem them for the beauty of their flowers. Being naturally biennial, the plants with single flowers rarely survive the second year; nor will those with double flowers continue much longer; so that unless young plants are annually raised to supply the place of the old ones, there will soon be a scarcity of them. There should be some strong roots of each sort kept apart for this purpose, which are not intended to flower: when these have shot up their flower-stalks about six inches high, they should be cut close to the bottom; each of these may be divided in the middle to make two cuttings, which should be planted in a soft gentle loamy soil, to an east exposure, where they may have only the morning sun. They may be planted near together, so as to be covered with hand or bell-glasses, which should be put over them after the cuttings have been well watered, and closely shut down, drawing the earth round the rim of the glasses to exclude the air; then the glasses should be shaded with mats every day when the sun is hot; and if the cuttings be gently refreshed with water once in seven or eight days, it will be sufficient, for too much moisture would rot them. After they are watered, the glasses should be shut down closely as before. In five or six weeks the cuttings will begin to put out roots, and will shoot up; then the glasses should be gradually raised on one side to admit the air to them, that they may be hardened, and prevented from drawing up weak. When they have made good roots, they should be carefully removed, and planted in an east border about eight or nine inches asunder, observing to shade and water them till they have again taken root; after which they will only require to be kept clean till autumn, when they may be transplanted into the borders of the pleasure-garden where they are designed to flower. The roots which are thus cut down, will send up more stalks than before; and when these are of a proper height, they may be cut off, and treated in the same way: so that when the roots are sound, two or three crops of these cuttings may be taken from them, and thus the old roots may be continued much longer than if they were permitted to flower, which will always secure a supply of good plants for the flower-garden.

4. *Hesperis Africana*; *African Rocket*. Stem very much branched and diffused; leaves lanceolate, petioled, sharply toothed, scabrous; siliques sessile; the stem, leaves, and pods of this plant are rough with three-barbed hairs; the flowers are flesh-coloured, with narrow, sublanceolate, bluish petals.—It is annual, and a native of Africa. If the seeds be permitted to scatter, the plants will come up without care,

and only require to be kept clean from weeds; or they may be sown in spring or autumn where they are to stand, for they do not bear transplanting well.

5. *Hesperis Verna*; *Early-flowering Rocket*. Stem upright, branched; leaves cordate, stem-clasping, serrate, villose; the stalk rises nine inches high, branching towards the top; the flowers are produced in loose panicles at the ends of the branches, they are of a lively purple colour; and those plants which rise in the autumn, flower in the spring. The seeds sown in the autumn succeed much better than those sown in the spring.

6. *Hesperis Lacera*. Leaves runcinate; siliques tricuspidate. It is a low annual plant, with pointed leaves, having the borders indented as if torn; the corolla is purple, and the flower has an unpleasant smell.—Native of Portugal and the south of France. If the seeds be sown in the spring upon sheltered borders where the plants are to remain, and they are thinned and kept clean from weeds, the plants will flower in July, and produce ripe seeds in autumn.

7. *Hesperis Laciniata*. Stem branched; leaves unequally jagged; corolla sulphur-coloured; root biennial; the whole plant villose with short hairs; stalks round.—Native of Piedmont about *La Briga* and *Sospello*, on rocks exposed to the sun.

8. *Hesperis Pinnatifida*. Leaves serrate, superior lanceolate, inferior winged on the under side. It flowers in June.—Native of the shady woods of Kentucky and Tennessee.

Heuchera; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-cleft, rounded, narrow; clefts obtuse. *Corolla*: petals five, inserted into the edge of the calix, oval-linear, the length of the calix. *Stamina*: filamenta five, subulate, upright; antheræ roundish. *Pistil*: germen roundish, half five-cleft, ending in straight styles, the length of the stamina; according to Gærtner, permanent, subulate-setaceous, long, diverging; stigmas blunt. *Pericarp*: capsule ovate, acuminate, half five-cleft, two-beaked, two-celled, the beaks bent back; according to Gærtner, inferior, closely barked by the calix, opening by a hole within the styles. *Seeds*: many, small. **ESSENTIAL CHARACTER.** *Petals*: five; capsule two-beaked, two-celled. These plants are propagated by parting the roots in autumn, and should be planted in a shady situation: they will bear the open air in England.—The species are,

1. *Heuchera Americana*; *American Heuchera*, or *Sanicle*. Scapes almost naked; thyrses elongated; root-leaves seven-lobed, on long petioles, doubly and sharply crenate; root perennial; scapes a foot high, dividing at top into a loose panicle, sustaining many small hairy flowers of an obsolete purple colour.—It flowers in May; ripens seed in August; and is a native of Virginia.

2. *Heuchera Dichotoma*. Stem branched; peduncles two-flowered, axillary; leaves linear-lanceolate, opposite, entire on the stem. This species, in the appearance of the flower, recedes a little from the characters of the genus, but not so much as to justify the institution of a new genus for it. The whole plant is hairy; peduncle emerging laterally from the bosom of the divarications of the branches, erect, long, dilated at the base, two-flowered, with two small pedicels, of which one is longer than the other; seeds many, minute.—Native place uncertain.

Hibiscus; a genus of the class Monadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth double. *Outer*: many-leaved, permanent; leaflets linear, more rarely one-leaved, many-cleft. *Inner*: one-leaved, cup-shaped, half five-cleft, permanent, or five-toothed, deciduous. *Corolla*:

petals five, roundish, oblong, narrower at the base, spreading, fastened at the bottom to the tube of the stamina. *Stamina*: filamenta very many, united at bottom into a tube, at top (in the apex and surface of this) divided and loose. *Antheræ*: kidney-form. *Pistil*: germen roundish; style filiform, longer than the stamina, five-cleft at top; stigmas headed. *Pericarp*: capsule five-celled, five-valved; partitions contrary, doubled. *Seeds*: solitary or several, ovate, kidney-form. *Observe*. The fortieth species has the capsule ovate, with the inner calix inflated, and several seeds. The thirty-sixth, has the capsule globular, and the seeds solitary; the eleventh has the capsule globular, berried, and closed; the outer calix three-leaved and caducous; the inner, obscurely five-toothed, and permanent. The twelfth species has the outer calix one-leaved, crenate; the third, eighth, seventeenth, and eighteenth species, have the seeds woolly on all sides; the twenty-second species has the seeds woolly in the circumference; the capsule in some is ovate, in others long; the outer calix is from three to twelve-leaved. The twenty-first species has no outer calix.—The species are,

1. *Hibiscus Moscheutos*. Leaves ovate, acuminate, serrate; stem very simple; petioles floriferous; root perennial; stalk single, two feet high, or more; flowers large, purple. It is remarkable in this species, that the flower springs from the petiole of the leaf, as in *Turnera Ulmifolia*.—Native of Virginia and Canada, though Cornutus informs us that it originally came from the woods of Africa: this, the second, twenty-second, thirty-fifth, and fortieth species, are hardy enough to bear the open air in England; but the two first, and thirty-fifth, seldom flower in the open air of our climate, unless in very warm summers, though the roots will live when planted in a sheltered situation. The only way to have these plants flower here, is to keep the roots in pots, and to shelter them under a frame in winter, and in the spring plunge them into a gentle hot-bed, which will cause them to put out their stalks early, and when the stalks are so high as to reach the glasses, the pots may be removed into a glass-case; where, if they are duly supplied with water, and have plenty of air in hot weather, they will flower very well in July, and in warm seasons will ripen their seeds.

2. *Hibiscus Palustris*; *Marsh Hibiscus*. Stem herbaceous, very simple; leaves ovate, slightly three-lobed, tomentose underneath; flowers axillary; root perennial; the peduncles come out singly from the axils of the upper leaves; they are longer than the petiole, but do not spring from it, are jointed, and support one very large bright purple-coloured flower.—Native of moist ground in Virginia and Canada: flowers here in July and August. For its propagation, see the first species.

3. *Hibiscus Micranthus*; *Minute-flowered Hibiscus*. Leaves roundish, entire, serrate; corollas reflex, oblique; root annual; flowers minute, on the summit of the stem; seeds lanuginous.—Found by Kœnig in the East Indies. This plant, like the majority of those belonging to this genus, must be kept in a bark-stove, where some of them will make a most splendid appearance. The principal mode of propagating them is by seeds, sown on a good hot-bed in the spring. The plants should be afterwards removed into pots filled with light earth, and plunged into a fresh hot-bed, treating them afterwards in the same way as the *Amaranth*. The tender sorts must be plunged during autumn in the tan-bed, there to remain, to be treated like other tender plants from the West Indies, and allowed but little water in winter.

4. *Hibiscus Microphyllus*; *Minute-leaved Hibiscus*. Leaves oval, rough-haired, serrate in front; stem shrubby; peduncles axillary, solitary, the length of the leaves, jointed

towards the top, thicker.—To be propagated as the preceding species.

5. *Hibiscus Urens*. Tomentose: leaves kidney-shaped, crenate; calices woolly. This herb is slightly stinging. Peduncles usually longer than the leaf; flowers axillary, two or three together, subsessile, glomerate; corolla small in proportion to the calix; purple.—Native of the Cape of Good Hope. This, together with the sixth, the twenty-fourth, twenty-eighth, and thirty-ninth species, require the protection of the green-house, Cape-stove, or glass-case.

6. *Hibiscus Præmorsus*; *Round-leaved Shrubby Hibiscus*. Leaves roundish, tooth-serrate, retuse, pubescent; the leaves are as it were truncate in the middle, crenulate, five-nerved, and soft; the flowers are small and yellow; the capsules small, five together, tubercled, with a point.—This beautiful shrub flowers from June to August, and is a native of the Cape of Good Hope. For its propagation and culture, see the preceding species.

7. *Hibiscus Cordifolius*; *Heart-leaved Hibiscus*. Arboreous, tomentose: leaves cordate, ovate, serrate; flowers peduncled, terminating; calix many-leaved, linear, long: the flower is middle-sized.—Native of South America. For its propagation and culture, see the third species.

8. *Hibiscus Rigidus*. Suffruticose, hirsute: branches simple; leaves oblong, serrate; limb of the corolla reflex; seeds woolly; the twigs long, filiform, quite simple, stiff; the stipules erect, bristle-shaped, stiff; the peduncles axillary, one-flowered.—Native of Ceylon. For its propagation and culture, see the third species.

9. *Hibiscus Sororius*. Leaves cordate, crenate, scabrous; outer calices round, dilated at the end; stem herbaceous or suffruticose, columnar, hairy all over, supported by trees; peduncles axillary, the length of the leaves, solitary, pubescent, one-flowered.—Native of Surinam. For its propagation and culture, see the third species.

10. *Hibiscus Cancellatus*. Stem weak, rough with hairs; leaves cordate, serrate; calices globular, having twenty subulate rays, rough with hairs; peduncles axillary, one-flowered, longer than the petioles.—Native of Surinam. For its propagation and culture, see the third species.

11. *Hibiscus Populneus*. *Poplar-leaved Hibiscus*. Leaves cordate, quite entire; stem arboreous. It is a tree fifteen feet or more high, with a trunk larger than a man can compass; the wood is white and soft, and the bark like that of the Lime-tree; the branches long and spreading; corolla large, yellowish white, inclining to green, becoming red as it decays; without scent.—Native of sandy soils in the East Indies, where it produces flowers plentifully during the greatest part of the year. For its culture and propagation, see the third species.

12. *Hibiscus Tiliaceus*; *Lime-tree-leaved Hibiscus*.—Leaves cordate, roundish, undivided, acuminate, crenate; stem arboreous; outer calix ten-toothed. This rises from eight to ten, twelve, and fifteen feet high, but has rather a smaller trunk than the preceding species, dividing into several spreading branches towards the top, which are covered with a brown bark and a woolly down; the flowers are produced towards the upper part of the twigs, from the axils, on peduncles an inch long, branched, and supporting several flowers, forming all together loose spikes. In figure and colour they resemble the foregoing, but they are smaller, and roughish on the outside, nor are they so curled and wrinkled; on the lower part of the neck, instead of the five-leaved rose which there is in that, we have a large, round spot, of a dusky red purple colour.—Native of the East Indies, and of almost every country within the tropics. This plant

flowers in the second year, if brought forward; otherwise not before the third or fourth. It will bear the open air in summer in a warm situation, but will not make any great progress. In the inland of Otaheite they make matting of the bark; also ropes and lines, from the size of an inch to that of a small packthread; and fishing-nets. They also suck the bark for food when the bread-fruit fails: and in New Caledonia the inhabitants frequently subsist on it, though it is an insipid food, affording very little nourishment. These accounts are attested by Hawksworth and Forster.

13. *Hibiscus Simplex*. Leaves cordate, three-lobed, repand, quite entire; stem arboreous, entirely simple.—Native of Asia. Propagated in the same way as the third species.

14. *Hibiscus Ovalifolius*. Leaves oval and subangular; outer calices five-leaved. The flowers have the size and appearance of those of the thirty-third species. Seeds villose. For its propagation and culture, see the third species.

15. *Hibiscus Rosa Sinensis*; *Chinese Rose Hibiscus*. Leaves ovate-acuminate, serrate; stem arboreous. In India it attains to the size of an ordinary tree; with us it is a round-stemmed, erect shrub, with alternate spreading branches, that are wandlike, leafy, brownish green, and nearly smooth. Flowers axillary, solitary, peduncled, large, of a deep scarlet colour; peduncles twice as long as the petioles, round, straight, thicker towards the top, with a joint beyond the middle.—It is extremely common in the gardens of China and the East Indies, but its native country is unknown. Loureiro however affirms that it is spontaneous, as well as cultivated, both in China and Cochin-china; and that it is so common in the latter, that they have entire hedges of it to their gardens. It has been long known from its appearance on Chinese screens and paper-hangings. The variety with double flowers is most frequently cultivated both in the East and in European hot-houses; it is indeed rarely seen with single ones. Loureiro remarks also that the double-flowered white variety is more difficult to cultivate, and differs a little from the others in having gash-serrate leaves. He likewise mentions another variety with large, double, brick-coloured flowers. But in so favourite a plant we should not be surprised if there were many more varieties. Rumphius says, that the white-flowered variety is not esteemed in the East, for the inhabitants of India are extremely partial to whatever is red, which they consider as a colour tending to exhilarate. They form these handsome flowers into garlands and festoons on all occasions of festivity, and even in their sepulchral rites. They are put also to a use which seems very inconsistent with their elegance and beauty, that of blacking shoes, from which they derived the name of *Rosæ Calceolariae*, and Shoe-flower. The women employ them to colour their hair and eye-brows black. Mr. Miller, who cultivated this flower as far back as the year 1731, informs us that he had never seen it with single flowers, which even now are rarely met with in our stoves. With double flowers it is common, thrives well, and is in blow during the greatest part of the summer. The single flowers are certainly of short duration, but that defect is compensated by their curious and beautiful structure. This most splendid and beautiful plant is perennial, and may be propagated by cuttings, but requires the protection of a hot-house or of the bark-stove.

16. *Hibiscus Brasiliensis*; *Brasilian Hibiscus*. Leaves cordate, toothletted; outer calix double the length of the other; stem shrubby; branches rough with hairs; stipules awl-shaped; peduncles one-flowered, longer than the leaves.—Native of Brazil. For its propagation and culture, see the third species.

17. *Hibiscus Hirtus*; *Hairy Hibiscus*. Leaves lanceolate,

ovate, acuminate, serrate; branches scabrous; stem herbaceous. This is a small plant, with a purple corolla and woolly seeds.—Native of the East Indies. For its propagation and culture, see the third species.

18. *Hibiscus Phoeniceus*. Leaves ovate, acuminate, serrate; peduncles jointed, thickened above the joints; lobes longer; calices naked; seed woolly.—Linneus has called this a variety of the preceding, but it appears to be a distinct species. It is a very beautiful shrub, blows in our stoves the whole summer, and is highly ornamental with its deep red flowers. For its propagation, see the third species.

19. *Hibiscus Mutabilis*; *Changeable Rose Hibiscus*. Leaves cordate, five-angled, obscurely serrate; stem arboreous, pale, single, smooth, spreading out wide into leafy branches at top, the wood resembling that of the fig; petioles rough, thick, three or four inches in length; peduncles thicker towards the top, sometimes tinged with red, sustaining large handsome flowers, which alter their colour; for at their first opening they are white, then they change to a blush rose colour, and as they decay turn to a purple. In the West Indies all these changes take place in one day; but in England, where they last nearly a week, the changes are not so sudden.—It is a native of the East Indies and Japan. The French first carried the seeds to their settlements in the West Indies; and the inhabitants of the British colonies there, being supplied with the seeds from them, have given it the name of Martinico Rose. It varies with double flowers, from which the single is frequently produced; but the seeds of the single seldom vary to the double. It blows in our stoves in November and December, and is much cultivated in the gardens of China and Cochin-china. The plants of this sort should not be quite exposed to the open air the first season; and the first winter will require the warmth of a moderate stove; but as they acquire more strength, they will need less care, for they will bear the open air in summer in a warm sheltered situation, and will survive the winter in a good green-house, provided they have not too much moisture; but the plants thus hardly treated will not make so great progress, nor flower so well, as with a little additional warmth; and if too tenderly managed, will draw up weak, and be less likely to flower. In England, as well as in its native country, it usually flowers in November.

20. *Hibiscus Spinifex*; *Prickly-fruited Hibiscus*. Leaves cordate, crenate, undivided; capsules set with spines standing out. It flowers here in July.—Native of the West Indies. For its propagation and culture, see the third species.

21. *Hibiscus Solandra*; *Maple-leaved Hibiscus*. Leaves subcordate, three-cusped, serrate; calices uncalicled; root annual; stalk upright; racemes terminating, upright, villose, two inches long; flowers alternate, stiff, four or five lines wide; peduncles upright, round, villose, jointed at the tip, becoming twice or thrice longer when in fruit; filaments shorter than the corolla. It flowers in July and August.—Native of the Isle of Bourbon. For its propagation and culture, see the third species.

22. *Hibiscus Syriacus*; *Syrian Shrubby Hibiscus*, or *Althæa Frutex*. Leaves wedge-form, ovate, gash-serrate towards the end; stem arboreous. It rises to the height of six or seven feet, sending out many woody branches covered with a smooth gray bark; the flowers come out from the wings of the stalk at every joint of the same year's shoot; they are large, and shaped like those of the Mallow, having five large roundish petals, which join at their base, spreading open at the top in the shape of an open bell: they appear in August, and if the season be not over warm, there will be a succession of flowers during a part of September. It is commonly called

Althæa Frutex by the nursery gardeners, who propagate the shrubs for sale: there are four or five varieties, which differ in the colour of their flowers; the most common has pale purple flowers with dark bottoms; another has bright purple flowers with black bottoms; a third, white flowers with purple bottoms; a fourth, variegated flowers with dark bottoms; a fifth, pale yellow flowers with dark bottoms; but the last is very rare at present in the English gardens; and a sixth with double flowers.—It is a native of Syria, and very much cultivated for hedges in Japan and Cochin-china. It is propagated by seeds, which should be sown in pots filled with light earth at the latter end of March, and plunged into a gentle heat to forward the growth of the seeds. When the plants appear, they must be inured to the open air, and in May the pots may be plunged into the ground in a border exposed to the east, where they may have the morning sun. They will require nothing but weeding and watering during the first summer, but in autumn it will be proper to remove the pots under a common frame, to screen them from the frost; or, where there is not such conveniency, they may be plunged close to a hedge, pale, or wall, or to a good aspect; and in severe frosts they should be covered with mats, straw, or other light covering; for although these plants, when they have obtained strength, will resist the cold of our winters, yet the young plants, the shoots of which are tender, frequently receive injury from the first frost of autumn; so that if they are not screened the first year, they are often killed to the ground. Towards the latter end of March will be a good time to transplant them. The spot of ground prepared to receive them should then be divided into beds four feet broad, with paths of two feet broad between them. The plants must then be shaken out of the pots with the earth adhering to them, carefully separated, for their roots are very tender and apt to break with little force, and replanted about nine inches asunder in the beds; so that if four rows be planted in each bed, there will be six inches allowed between the outside rows and the paths. The ground should be gently closed about the roots, to prevent the air penetrating to them; and if a little old tanner's bark or mulch is laid over the surface of the beds, it will prevent the earth from drying, and be of great use to the plants. During the succeeding summer they must be kept free from weeds; and should the next winter prove severe, it will be prudent to cover the plants again in autumn, especially if they shoot late in the season, or the autumn prove cold and moist, for then the plants will be in great danger of having their tops killed. In these beds they may remain two years, by which time they will be fit to transplant to where they are intended to remain; for if kept longer in the nursery, they will not remove so well. The best time for transplanting these plants is the end of March, or the beginning of April, for they seldom begin to shoot till the end of April, or the beginning of May; they should have a light soil, not too wet, for in strong land their stems grow mossy, and they never thrive after. They may also be propagated by layers; and by cuttings, which, if planted the latter end of March, in pots filled with light earth and plunged into a gentle heat, will take root; but the plants thus raised are not so good as the seedlings. The several varieties may be increased by grafting upon each other, which is the common method of propagating those with striped leaves.

23. *Hibiscus Ficulneus*; *Fig-leaved Hibiscus*. Leaves palmate, five-cleft; stem prickly; flowers peduncled. The flowers come out singly from the axils; they hang down, are small, and white with purple bottoms, and are succeeded by short obtuse capsules. They open only when the sun shines,

and that but for a few hours in the morning or about noon; and appear from June to August.—Native of Ceylon. For its propagation and culture, see the third species.

24. *Hibiscus Speciosus*; *Smooth Hibiscus*. Leaves palmate, smooth; segments lanceolate, serrate; stem, peduncles, and calices, even.—It is a native of South Carolina, and flowers in September. Perennial. See the fifth species.

25. *Hibiscus Sabdariffa*; *Various-leaved Hibiscus*. Leaves serrate, the lower ovate, undivided, the upper seven-parted; stem unarmed; flowers sessile; root annual, single, descending; flowers axillary, solitary, largish; petals veined, of a very pale sulphur colour, with a dark blood-red bottom. It is a native of India, and has been long known in England. Gerard and Parkinson call it *Thorny Mallow*. It flowers from June to September. In the West Indies it is known by the name of *Red-sorrel*. The calices and capsules freed from the seeds make very agreeable tarts; and a decoction of them sweetened and fermented is commonly called there *Sorrel cool drink*, which is a small diluting liquor, much used in our colonies, and reckoned very refreshing in those sultry climates. See the next species: and for its propagation and culture, see the third species.

26. *Hibiscus Cannabinus*; *Hemp-leaved Hibiscus*. Leaves serrate, the upper palmate, five-parted, having one gland underneath; stem prickly; flowers sessile; root annual; flowers axillary; the corolla large, of a pale sulphur colour, with a dark purple bottom. The bark of this and of the foregoing species is full of strong fibres, which the inhabitants of the Malabar coast prepare and make into cordage, and it seems as if it might be wrought into fine strong thread of any size.—Native of the East Indies. For its propagation and culture, see the third species.

27. *Hibiscus Surattensis*; *Prickly-stalked Hibiscus*. Prickly, with prickles curved back; leaves five-lobed; outer calices appendicled; stipules half-cordate; flowers peduncled; stem round, upright, stiff, two feet high, spotted with purple towards the top; corolla yellow, with a dark purple base.—The leaves are gratefully acid, and are eaten in the East Indies and Cochin-china, where it is a native: they also assist in dissolving hard tumors, but for that purpose the roots are thought to be most efficacious. Annual: flowers in July. See the third species.

28. *Hibiscus Pedunculatus*. Hirsute: leaves five-lobed, toothed; peduncles axillary, one-flowered, elongated.—Native of the Cape of Good Hope. For its propagation and culture, see the fifth species.

29. *Hibiscus Manihot*; *Palmated-leaved Hibiscus*. Leaves palmate-digitate, seven-parted; stem and petioles unarmed. It rises with an herbaceous smooth stalk three or four feet high. The flowers are produced from the wings of the stalks towards the top, standing on short peduncles; they are composed of five large sulphur-coloured petals, which, when open, spread five inches wide; they have a dark purple bottom; and are succeeded by large, pyramidal, five-cornered, erect seed-vessels, which are filled with pretty large seeds, having little smell or taste. In Japan the mucilage of the root of this plant is employed to give consistence to paper. It flowers in July and August.—Native of China and Japan. This species will produce flowers and perfect seeds in the first season. The plants may be preserved by a moderate warmth through the winter, though few persons will take that trouble after they have ripened their seeds, as the young plants make a better appearance.

30. *Hibiscus Abelmoschus*; *Target-leaved Hibiscus*. Leaves subpeltate, cordate, seven-angled, serrate; stem hispid, herbaceous, three or four feet high, sending out two or

three side branches, all of which, as well as the stem, are hairy. The flowers come out from the wings of the stalk upon pretty long peduncles, which stand erect; they are large, of a sulphur-colour, with dark purple bottoms, and are succeeded by pyramidal five-cornered capsules, filled with large seeds, of a very musky odour, so that a few of them are sufficient to perfume a whole room. They may undoubtedly be used in scenting powders and pomatums, instead of the animal musk, which is a scarce and dear commodity; and are accordingly put to that use in Paris. In Arabia and Egypt, they grind these seeds, and mix the powder with their coffee, to render it more agreeable to the head and stomach. The official names are, *Abelmoschus*, from the Arabic *Abelmosch*, grain or seed of musk; and *Bamia Moschata*. These seeds seem to have a claim, as a medicine, to the cordial and nervine virtues, derived from most other substances of that class. In its native country it is biennial, but seldom survives a year here.

31. *Hibiscus Esculentus*; *Eatable Hibiscus*. Leaves five-parted, pedate; inner calices bursting at the side. This rises with a soft herbaceous stalk, from three to five feet high, dividing at top into many branches. The flowers are axillary, of a pale sulphur colour, with dark purple bottoms; small, and of very short duration, opening with the rising sun, but fading long before noon in warm weather. The capsule is remarkable for bursting on the side.—It is common in the West Indies, where the inhabitants cultivate it for the capsules, which they gather green, to put into their soups and pepper-pots. They are generally boiled separately, and added just before the messes are taken off the fire; but the seeds may be boiled in broth, like barley or any other ingredient, for they are not so mucilaginous. The pods, boiled and buttered, make a rich dish: but they are used only in private families in this form. They are full of a nutritive mucilage. It is known in Jamaica by the name of the *Okro* plant; in China and Cochin-china, it is cultivated in gardens, for the beauty and colour of the flower, which is nevertheless void of scent: with us it is annual, and flowers in June. It will live in a warm border, and thrive for a time in a good season; but with the first cold or bad weather, the leaves drop off: it seldom flowers, and never perfects seeds; so that it requires shelter, especially in cold wet weather.

32. *Hibiscus Clypeatus*. Leaves cordate, angular; capsules turbinate, truncate, hispid. This shrub is the height of a man. Stem upright, branched, round, pubescent; peduncles one-flowered; corollas pale, sometimes dusky yellow. It is found, but not in abundance, in coppices near the coast of the island of Jamaica, where it is commonly called *Congo Mahoe*; the negroes affirming, that it came originally from Africa. For its propagation and culture, see the third species.

33. *Hibiscus Vitifolius*; *Vine leaved Hibiscus*. Leaves five-angled, sharp, serrate; stem unarmed; flowers drooping; peduncles axillary, solitary, one-flowered, leafless, the length of the leaves; corolla large, yellow, with a dark purple base: annual.—Native of the East Indies. For its propagation and culture, see the third species.

34. *Hibiscus Zeilanicus*. Leaves cordate, hastate; peduncles alternate, one-flowered, jointed; corolla flesh-coloured.—Native of the island of Ceylon. For its propagation and culture, see the third species.

35. *Hibiscus Virginicus*. Lower leaves cordate, acuminate, serrate; upper hastate; stem green, upright; peduncles one-flowered, solitary, axillary, forming something of a naked raceme at top.—Native of salt marshes in Virginia. See the fourth species.

36. *Hibiscus Pentacarpus*. Lower leaves cordate, angular; upper subhastate; flowers nodding a little; pistil dropping; root perennial; stem three feet high, narrow; peduncles axillary, on the top of the plant, solitary, naked, longer than the petiole, one-flowered; corolla spreading, pale red, nodding a little.—It grows near Venice, in marshy places, and was also found near Astracan. Though the roots will live in the open ground, yet our summers are not warm enough to bring it to flower: the seeds therefore should be sown in a hot-bed, and when the plants are fit to remove, they should each be planted in a separate small pot, and plunged into a moderate hot-bed, allowing them sufficient air in warm weather. It may stand in the open air in summer, but will seldom flower, unless kept in a deep frame, where it will continue, and flower for several years. See the fifth species.

37. *Hibiscus Hastatus*. Hoary; leaves oblong, simple, three-lobed at the base, quite entire; raceme terminating.—Native of the Society Isles. See the third species.

38. *Hibiscus Fraternus*. Leaves three-lobed; outer calices with round rays, mucronate and concave at the tip; stem herbaceous, smooth and even, as is the whole plant; corolla yellow.—Native of Surinam. See the third species.

39. *Hibiscus Ethiopicus*. *Dwarf Wedge-leaved Hibiscus*. Leaves subcuneate, slightly three-toothed, the upper ones opposite; flowers terminating. This is a small shrub. Flowers peduncled, solitary, the peduncles shorter than the leaf.—Native of the Cape of Good Hope. For its culture and propagation, see the fifth species.

40. *Hibiscus Trionum*; *Bladder Hibiscus*. Leaves three-parted, gashed; calices inflated. It rises with a branching stalk a foot and a half high, having many short spines, which are soft. The flowers come out at the joints of the stalks, upon pretty long peduncles; each flower is composed of five petals, which spread open at the top, and form an open bell-shaped flower: these have dark purple bottoms, but are of a pale sulphur colour above, tinged sometimes partially with pale purple on the outside, where they are also ribbed; the corolla becomes wholly purple after it has folded up again. This is an annual plant, growing naturally in some parts of Italy, and Austria.—It has been long known in the English gardens by the title of *Venice Mallow*: Parkinson also calls it *Mallow*, or *Flower of an Hour*, and *Good Night at Noon*, or *Good Night at Nine*. The flowers are certainly of short duration, and in hot weather continue but few hours open. There are several varieties; two are natives of the Cape of Good Hope. This plant is propagated by seeds, which should be sown where the plants are designed to remain; for they do not bear transplanting well. If the seeds are sown in autumn, the plants, coming up early in the spring, will flower in the summer, and those which are sown early in the spring, will succeed them; so that by sowing them at three different seasons, they may be continued in succession till the frost stops them. They only require clearing from weeds, and thinning them where they are too close; and if the seeds are permitted to scatter, the plants will come up full as well as when sown, so that it will maintain its situation, unless it be weeded out.

41. *Hibiscus Elatus*. Leaves cordate, roundish, entire; peduncles very short, one-flowered; calix ten-toothed. This is a tree, growing to a considerable size: the wood is of a dark olive colour; the bark pretty smooth, and the trunk tall and straight; the flowers are large and open, not unlike those of the yellow lily either in size or appearance: it is reckoned excellent timber. All the tender parts of the tree abound with a delicate mucilage, which may be used instead of the more common medicines of this tribe. The bark

is made into ropes of all sorts.—Native of Jamaica, where it is called *Mahot* or *Mahoe-tree*. See the third species.

42. *Hibiscus Clandestinus*. Stem virgate, rough with hairs, shrubby; leaves ovate, sharp, somewhat three-lobed; flowers minute, closed, axillary, solitary; peduncles longer than the leaf, upright, jointed, and thicker towards the tip; corolla whitish, villose, scarcely larger than the calix, becoming violet coloured as it withers; petals ovate, never expanding; *Seeds*: blackish, with a very white wool drawn over them.—Native of Senegal. For its propagation and culture, see the third species.

43. *Hibiscus Tomentosus*. Leaves heart-shaped, angular, serrate, tomentose; stem arboreous.—Native of the West Indies: see the third species.

44. *Hibiscus Cordifolius*. Leaves heart-shaped, hirsute, crenate; leaves lateral; stem arboreous, branched.—Native of the West Indies: see the third species.

45. *Hibiscus Bahamensis*. Leaves oblong, cordate, smooth, toothletted, hoary underneath, with very large flowers. It has a perennial root, but annual stalks, at the tops of which the flowers are produced: they are very large, and of a light purple colour, with dark bottoms, and are succeeded by short capsules.—Native of the West Indies. For its propagation and culture, see the third species.

Hickory. See *Juglans*.

Hieracium. A genus of the class Syngenesia; order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common, imbricate, ovate; scales several, linear, very unequal, longitudinal, and incumbent. *Corolla*: compound, imbricate, uniform: corollules hermaphrodite; numerous, equal. *Proper*: monopetalous, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubulous. *Pistil*: germen subovate; style filiform, the length of the stamina; stigmas two, bowed back. *Pericarp*: none; calix converging, ovate. *Seeds*: solitary, obtusely four-cornered, short; down capillary, sessile; receptacle naked. **ESSENTIAL CHARACTER.** *Calix*: imbricate, or caliculate, ovate; down simple, sessile. *Receptacle*: naked. Most of the plants of this genus are reputed to be weeds, and very few of them are cultivated, except in botanic gardens. If their seeds be permitted to scatter, they will in general propagate themselves; and being mostly perennial, they may all be increased by parting the roots. The seeds should be sown on a border with an eastern aspect, in March; and when the plants come up they must be kept clean from weeds, till they are strong enough to remove, which will be by the beginning of June; then they should be transplanted to a shady border of undunged ground, at six inches' distance; observing to water them if the weather should prove dry, till they have taken new root; after which, if they are kept clean from weeds, they will require no other culture: in the autumn they should be transplanted where they are designed to remain: in the following summer they will flower and produce ripe seeds, and the roots will continue some years, if not planted in a rich moist soil, which frequently occasions their rotting in winter. They may also be propagated by parting their roots in autumn.—The species are,

* *With a one-flowered Scape.*

1. *Hieracium Incanum*; *Hoary Hawkweed*. Leaves quite entire, somewhat toothletted, lanceolate, scabrous; root thick, perennial, blackish on the outside, white within; stems round, upright, twice or thrice the length of the leaves; corolla yellow.—Native of the mountains of Austria, Carniola, and the Palatinate: flowering in June.

2. *Hieracium Pumilum*; *Dwarf Hawkweed*. Leaves ovate; petioles dilated; scapes with one or two flowers;

roots perennial, creeping, branched; stems half a foot in height, generally procumbent and reddish; corolla pale yellow, broadish, with five teeth at the end. Found upon the Alps, and Glaciers, in Switzerland, Savoy, and Dauphiny, among the pebbles and fragments of rocks.

3. *Hieracium Alpinum*; *Alpine Hawkweed*. Leaves oblong, entire, toothed; scape almost naked; calix hairy. This species is chiefly distinguished by the whole of the plant, but especially the calix, being covered with long white hairs; and the scales of the calix being remarkably loose: root perennial and fibrous; stalk about five inches high, generally terminated by one large flower, but seldom more than two. It flowers in July and August.—Native of Lapland, Switzerland, Dauphiny, Savoy, Carniola, Silesia, and the mountains both of Wales and Scotland.

4. *Hieracium Taraxaci*. See *Apargia Taraxaci*. Leaves lanceolate, toothed, smooth; scape almost naked; calix hirsute; stalk six inches high, smooth towards the base, but hairy near the top, bearing a single yellow flower; perennial: flowering in July.—Native of the mountains of Switzerland, Scotland, and Wales.

5. *Hieracium Alpestre*. Leaves lanceolate, toothed, smooth; scape with a leaf and a flower or two; calix hirsute, cylindric; root-leaves on short petioles, having large teeth about the edge, almost linear, broader at the end; corolla short, not large, yellow: Perennial.—Native of Austria and Silesia.

6. *Hieracium Venosum*; *Vein-leaved Hawkweed*. Leaves wedge-shaped, rough with hairs; scape very thick, upright, shrubby; stem branched, leafless; flowers small, yellow.—Native of Virginia and Maryland.

7. *Hieracium Pilosella*; *Mouse-ear Hawkweed*. Leaves quite entire, ovate, tomentose underneath; stem throwing out runners; root perennial, creeping; flowers early, an inch in diameter; corolla pale yellow, or sulphur colour, composed of about fifty florets, the outer having a broad purple stripe on the under side; each floret has five teeth at the end. According to Linneus, the flowers of this plant commonly open at eight in the morning, and close about two in the afternoon. An insect of the coccus or cochineal kind is found at its roots: but it has not been observed in England. It differs from other plants of this class in being less bitter, and more astringent. On account of this astringency it was admitted into the shops as a medicine, under the name of *Auricula Muris*, or *Mouse-ear*; but it is now little regarded. Culpeper says that the green leaves bruised, and applied to any cut or wound, will soon heal it; and Meyrick and Hill both recommend it as an excellent astringent, and say that the powder may be given in immoderate menstrual discharges, and other bleedings, whether internal or external. A strong decoction of it is good in purges attended with bloody stools, also for the bleeding of the piles; and the leaves boiled in milk are a good external application for the same purpose. It flowers from May to September, and is very common on dry pastures, sunny banks, and walls.

** *With a many-flowered Scape.*

8. *Hieracium Dubium*; *Creeping Hawkweed*. Leaves entire, ovate, oblong; runners creeping. There is a diversity of opinion among Botanists concerning this plant. It appears considerably to resemble the foregoing species, but is larger, and has the leaves hairy, not tomentose underneath; corollas pale yellow on both sides. Kroker distinguished it from the *Mouse-ear*, by its having fewer (only two or three) flowers; by its lesser stature; entire leaves, on very short petioles; having very few long hairs; and being in other respects smooth: it flowers in July and August. Sheep are reported

to eat this plant, although the Mouse-ear is reputed to be injurious to them.—Native of Sweden, Switzerland, Germany, Dauphiny, and in moist places upon the mountains of England, as near Rydall in Westmoreland.

9. *Hieracium Auricula*; *Narrow-leaved Hawkweed*. Leaves quite entire, lanceolate; runners creeping; root præmorse, with numerous simple fibres; scape upright, naked, scarcely half a foot high, having a few scattered hairs on it; flowers in a panicle, from three to six. It may be distinguished from the preceding species, by its having a higher stalk, and more flowers; longer, narrower leaves, more hirsute with shorter hairs; the flowers sulphur-coloured; the calix like the stalk, having black bristles scattered over it: it flowers in July, and is perennial.—Native of Lapland, Sweden, Switzerland, Germany, Dauphiny, and England, upon mountains: it is found on Dalehead, not far from Grass-mere, Westmoreland.

10. *Hieracium Cymosum*; *Small-flowered Hawkweed*. Leaves lanceolate, entire, hairy; scape almost naked, hairy at the base; flowers in a kind of umbel; root præmorse. According to Villars, this species is easily distinguished. The stem is straight, about a foot high, terminated by a cyme of flowers, so close that the peduncles are seen with difficulty, though they are branched. He mentions two varieties; one with red flowers, and another with from three or four to six scattered flowers, as large again as the common sort. Perennial. Flowering in June.—Native of Russia, Denmark, Germany, Switzerland, and Dauphiny.

11. *Hieracium Præmorsum*; *Truncate-root Hawkweed*. Leaves ovate, somewhat toothed; scape branched, upper flowers coming out first; root perennial, fibrous; flowers in a panicle containing frequently from sixteen to twenty. They are small, each supported on a simple pedicel, which has a lanceolate stipule at the base, forming altogether a sort of spike. This herb watches from seven o'clock in the morning to six in the evening, when the panicle of flowers also nods. It flowers in May and June.—Native of Sweden, Germany, Switzerland, and Siberia.

12. *Hieracium Aurantiacum*; *Orange-flowered Hawkweed*. Leaves entire; stem almost naked, quite simple, hairy, corymbiferous; root perennial, creeping; stipules very small, lanceolate; flowers eight or ten, on short pedicels, forming a short panicle; corolla dark red. It flowers from June to autumn, and varies much in the colour of the flower, from red to orange, and several shades of yellow. It is called by our old writers *Golden Mouse-ear*; and when of a dark colour, *Grim the Collier*.—Native of Austria, Switzerland, Silesia, Dauphiny, and Piedmont.

13. *Hieracium Gronovii*; *Gronovius's Hawkweed*. Stem panicled, almost naked; root-leaves obovate, quite entire, hairy.—Native of Virginia.

14. *Hieracium Gmelini*; *Gmelin's Hawkweed*. Stem panicled; root-leaves ovate, serrate, smooth; calix simple; scales eight or ten.—Native of Siberia.

15. *Hieracium Sanctum*; *Palestine Hawkweed*. Leaves lyrate, blunt-toothed; root thick, long, like *Naveus*, with one or two branches; corollas yellow.—Native of Palestine, the south of France, and the county of Nice.

16. *Hieracium Capense*; *Cape Hawkweed*. Lower peduncles higher; leaves oblong, toothed, scabrous; scape a foot high, even, with a few very small awl-shaped leaves alternately scattered over it; flower terminating from the axil of the leaves.—Native of the Cape of Good Hope.

***With a leafy Stem.

17. *Hieracium Poutanum*. Stem with one or two flowers; leaves lanceolate, toothed; root perennial, single, deep black-

ish; flower large; corolla yellow.—Native of the mountains of Savoy and Dauphiny, in pastures.

18. *Hieracium Paniculatum*; *Panicled Hawkweed*. Stem upright; leaves alternate, lanceolate, naked, toothed; panicle capillary; panicle terminating, variously branched, with very slender divaricating peduncles; bractes at the ramifications very short, bristle-shaped; flowers small.—Native of Canada.

19. *Hieracium Parvifolium*; *Leek-leaved Hawkweed*. Stem branched; leaves lanceolate linear, almost entire; root-leaves lanceolate, upright, with one or two sharp teeth, even, having a few villose hairs along the keel; stem-leaves minute, very few; corolla yellow. The whole plant, says Villars, has the smell of the wild lettuce in a greater degree than any of the Hawkweeds. Perennial.—Native of the south of France, the Valais, Austria, Silesia, and Italy.

20. *Hieracium Chondrilloides*; *Gum-succory Hawkweed*. Stem branched; stem-leaves elongate-toothed, smooth; root-leaves lanceolate, entire; peduncles from the upper axils of the leaves, the same height with the stem, solitary, almost naked, one-flowered; corolla yellow. It flowers in June and July, and is a native of the south of France, Austria, and Silesia.

21. *Hieracium Murorum*; *Wall Hawkweed*. Stem branched; root-leaves ovate, toothed; stem-leaf smaller. This plant varies exceedingly, as appears from the different figures which are given of it. The general appearance is as follows: Root simple, producing one slender stem, a foot or fifteen inches high, cylindrical, having soft hairs scattered over it, slightly striated, reddish towards the base, sometimes naked or nearly so, sometimes clothed with leaves nearly similar to the others, only more acute; flowers in a branched panicle, on separate peduncles, with each an awl-shaped bracte; calix of numerous, unequal, linear, lanceolate leaves, the lower one spreading; corolla yellow; seeds nearly cylindrical, furrowed, smooth, dark purple, crowned with a sessile down, as long as the seed; ray simple, the length of the calix. Linneus observes, that the flowers open about six in the morning, and close about two in the afternoon. Lightfoot says, that about eighteen days elapse between the first expansion of the flower and the ripening of the seed. Our old authors call it *French* or *Golden Lungwort*. There are many varieties.—Common in various parts of England.

22. *Hieracium Humile*. Stem few-flowered, scarcely higher than the lower leaves, which are hirsute and gashed.—Native place unknown.

23. *Hieracium Paludosum*; *Marsh Hawkweed*. Stem panicled; leaves clasping-toothed, smooth; calices hispid; root perennial; flowers single; peduncles smooth. Flowers open at six in the morning, and close again at five in the afternoon. Possibly it may be only a variety of the twenty-first species, though it has acquired from its place of growth so very different an appearance.—Native of many parts of Europe, in moist meadows and woods, and by the sides of mountains, rivers, and rivulets. It is found in several parts of the northern counties, and also in Scotland.

24. *Hieracium Lyratum*; *Siberian Hawkweed*. Stem many-flowered; leaves lyrate, smooth; calix and peduncles hispid.—Native of Siberia.

25. *Hieracium Cerinthoides*; *Honeywort Hawkweed*. Root-leaves obovate, toothletted; stem-leaves oblong, half-clasping; root perennial, black, branched, frequently ending abruptly; plant evergreen; peduncles one-flowered, ash-coloured, and hispid, with long hairs single from the axils. Gouan remarks that it varies in its native place, with a stem scarcely a hand in height, with two flowers and a single leaf, if any.—Native of the Pyrenees.

26. *Hieracium Amplexicaule*; *Heart leaved Hawkweed*. Leaves stem-clasping, heart-shaped, somewhat toothed; peduncles one-flowered, hirsute; stem branched, a foot high. The panicle has a pile between the hairs, by which it is almost tomentose. The constant characters of the species, in all its varieties, are,—the great quantity of glandular hairs, which give it the smell of baum or new honey; the openness of the lower scales of the calix; the russet-colour of the whole plant; and the hairs of the egret, brittle and elbowed at the base.—Native of the Pyrenean mountains.

27. *Hieracium Pyrenaicum*; *Pyrenean Hawkweed*. Leaves stem-clasping, obovate-lanceolate, toothed backwards; stem simple; calices loose. This species varies so much as not to be easily determined. One variety has a root perennial, fibrous, forming a tuft, whence spring several stems a foot and half high; peduncles several, solitary, from the upper axils, each terminated by one large yellow flower, in which the florets are separated and dispersed. Native of Dauphiny.—Another, stem two feet high, upright, slightly striated, hairy, branched only at top; peduncles or branches three inches long, axillary, alternate, clothed at top only with very small, loose, wandering scales; corolla yellow. Native of the Pyrenean mountains.—In a third variety, from a woody, perennial, brown, divided root, arise a few simple, round, upright stalks, striated, and more or less hispid at top, annual, from a foot to a foot and a half in height; peduncles three or four, (sometimes only a single terminating one,) axillary, solitary, almost of the same height, upright, hispid, striated, leafless, or having only one or two ciliate bractes; flower large and elegant, yellow. It flowers in August, and is a native of Austria.—A fourth variety has the stem-leaves much sagittate, with very acute earlets; peduncles long, one-flowered, swelling below the flower, black with hairs; down simple, sessile.—Native of Switzerland.

28. *Hieracium Molle*; *Soft-leaved Hawkweed*. Leaves lanceolate, almost entire, soft, the lower ones petioled; flowers on peduncles forming a kind of corymb; root perennial, blackish, bitten, and furnished with long, white, round fibres: it produces annually a simple, upright, striated, purplish, somewhat hairy, leafy stem, of about a foot or two in height; the top of which is divided into a few single-flowered footstalks of about an inch and half long, and a little hairy; corolla deep yellow, with antheræ and stigma of the same colour. It grows about the borders of the subalpine woods, flowering in July, and producing seeds in August: when cultivated in a garden, it flowers about the end of May or beginning of June, and grows more branchy from the bosoms of the leaves; but in other respects does not change its habit.—Native of Austria: found also in Scotland in the year 1760.

29. *Hieracium Stipitatum*. Stem branched, with only a leaf or two; leaves toothed; down stiped. This plant grows a foot high or higher. From a perennial, bitten, oblique round root of about an inch and half long, about the thickness of a quill, and of a palish brown colour, it produces annually a solitary, round, somewhat striated, fistulous stem, smooth below, and above rather hispid, with scattered dark hairs; the corollules are yellow, and five-toothed; antheræ brown. It is found on hilly meadows, flowering in June and seeding in July.—Native of Austria.

30. *Hieracium Villosum*; *Villose Hawkweed*. Stem branched; leaves hirsute; root-leaves lanceolate-ovate, toothed; stem-leaves clasping, heart-shaped; root-leaves lanceolate, broadish. It varies, says Jacquin, so much in different soils, that it is difficult to give such a description as will agree with every individual; root knobbed, unequal, blackish, perennial, with round whitish fibres; flowers large, handsome, yellow;

calix loose, with black dots and much white wool; seeds short, with a sessile simple egret, appearing toothed with a magnifier. The hairs on this plant are almost all very white, long, and feathery; there are some however shorter, and terminated by a gland.—Both it and its varieties are natives of Dauphiny, Switzerland, Austria, Bohemia, and Silesia, in mountain pastures. It has also been found on the moist rocks of Ben Nevis, a high mountain in Scotland.

31. *Hieracium Glutinosum*; *Clammy Hawkweed*. Leaves lanceolate, runcinate, somewhat scabrous; flowers in umbels; stem striated; root annual.—Native of the south of France.

32. *Hieracium Kalmii*; *Kalm's Hawkweed*. Stem upright, many-flowered; leaves lanceolate, toothed; peduncles tomentose at the top of the stalk, alternate, commonly simple and one-flowered; with fewer linear bractes; flowers small, terminating, upright.—Found by Kalm in Pennsylvania.

33. *Hieracium Undulatum*; *Wave-leaved Hawkweed*. Stem branched; leaves elliptic, toothed, waved, hairy; hairs plumose.—Native of Spain.

34. *Hieracium Sprengerianum*; *Branched Hawkweed*. Stem branched; leaves half stem-clasping, oblong, repand, hispid; calices terminating, several, peduncled, scatteringly haired.—Native of Portugal.

35. *Hieracium Spicatum*; *Hairy Hawkweed*. Stem many-flowered; leaves stem-clasping, hairy, thinly toothed. The smallness and great number of flowers in this plant, joined to their conical form, and the disposition of the branches, which subdivide and divaricate at right angles, distinguish this plant from all the known *Hieracia*.—Native of Switzerland, Dauphiny, and Piedmont. Found also in woods in the south part of Scotland.

36. *Hieracium Subaudum*; *Shrubby Hawkweed*. Stem upright, many-flowered; leaves ovate-lanceolate, toothed, half stem-clasping; root fibrous, perennial, yellowish ash-colour on the outside, white within; branches subdivided, and the last subdivisions one-flowered; peduncles erect, whitish, with pubescence, a little thicker at top, having scales scattered over them forming a thin corymb; flowers yellow, an inch and half in diameter. They open at seven in the morning, and close between one and two in the afternoon, in July, August, and September. It varies with leaves covered with a short and just perceptible down, so as to have the appearance of being smooth; with one flower only on a stem; and with broad lanceolate leaves on short footstalks.—Native of most parts of Europe; not common in Great Britain.

37. *Hieracium Umbellatum*; *Umbelled or Bushy Hieracium*. Leaves linear, somewhat toothed, scattered; flowers in a kind of umbel; root perennial, præmorse or truncate, yellow on the outside, white within, having many fibres in bundles; stem from two to four feet high, upright, simple, round, striated, hollow, nearly smooth, green, frequently dotted with red, alternately, especially towards the top, dividing into branches. Flower large, yellow, containing as far as ninety-seven florets. This species is often confounded with the preceding by intermediate individuals partaking of the characters of both, and perhaps they are more distinguishable by the eye than by the specific differences. Mr. Curtis thinks that the most obvious character of this species consists in the shortness of its leaves. It is a strong-smelling plant, and in Scania is used as a dye, communicating to wool an elegant and beautiful colour. It flowers in July, August, and September.—Native of dry pastures in most parts of Europe. It is not common in England, but is found on the sandy or gravelly heaths about Hampstead, Barnet, and Charlton, in the neighbourhood of London; and near Hildersham and Gamlingay, in Cambridgeshire.

38. *Hieracium Halleri*. Leaves lanceolate, toothed, obscurely villose; stem somewhat branched, stiff, six or eight inches high, straight, stout, terminated by one, two, or three flowers, hirsute, with long lanuginose hairs, and others that are smaller placed on a black base, which gives a roughness to the stem; calix oval; scales lanuginose, separate, dirty gray, a little viscid.—Native of Switzerland, Savoy, and Dauphiny.

39. *Hieracium Valde Pilosum*. Stem straight, almost simple; leaves stem-clasping, woolly; calices imbricate. This is thought to be a variety of the thirtieth species.

40. *Hieracium Cydoriæfolium*. Stem straight, branching from the axils; leaves oblong, elliptic, half stem-clasping, toothed; calices hispid, blackish; flowers middle-sized, in a gray and blackish calix; perennial.—Native of Dauphiny.

41. *Hieracium Scorzonæfolium*. Leaves linear, lanceolate, glaucous, and hairy; stem oblique, hairy and hoary, few-flowered; root oblique, truncated, and perennial.—Native of the beds of torrents in the Alps, and in Dauphiny.

42. *Hieracium Glaucum*. Leaves lanceolate, glaucous; stem branched, stiff, a foot or eighteen inches high, having little oval, acuminate, sessile leaves at the divisions of the branches. Flowers middle-sized.—Native of Dauphiny.

43. *Hieracium Staticifolium*. Stem almost naked; leaves ligulate, obtuse, flower sulphur-coloured; root very thick and deep, frequently forked at the upper part, perennial; flowers large, pale-yellow, or sulphur-coloured, turning green in drying.—Native of Dauphiny, Piedmont, and Switzerland.

44. *Hieracium Saxatile*. Leaves roundish, quite entire; stem almost naked; receptacles hirsute, a few inches high, terminated by a few flowers; seeds blackish; their receptacle manifestly villose.—Native of Dauphiny and Italy.

45. *Hieracium Lawfonii*. Leaves oblong, villose, quite entire; stem straight, many-flowered; root thick, truncate, perennial, covered with russet membranes; the peduncles have two scales near the calix, and one leaf at their base: the hairs of the calix are in part glandular.—Native of Dauphiny, found also in the north of England.

46. *Hieracium Andryaloides*. Leaves densely tomentose, curled or sinuate at the base; stem spreading; root oblique, thick, perennial.—Native of Dauphiny.

47. *Hieracium Liottardi*. Leaves lanceolate, toothed; stem upright, two-flowered. This plant, which is cottony and small like the last, is distinguished by its lanceolate toothed leaves.—Native of Dauphiny.

48. *Hieracium Jacquinii*. Leaves pinnatifid at the base, hirsute, green; calicine hairs glandular; stem with about two flowers; root thick, oblique, fibrous, truncated, perennial; calix villose, blackish, with a few glandular hairs; egret sessile, with simple hairs, slightly toothed.—Native of Dauphiny.

49. *Hieracium Lanceolatum*. Stem straight, stiff; leaves lanceolate, toothed; flowers in a kind corymb; root perennial.—Native of Dauphiny.

50. *Hieracium Pulmonarioides*. Leaves lanceolate, tooth-sinuate, those on the stem sessile; peduncles proliferous; root perennial, oblique, thick, covered with scales; stem about a foot high, terminated by several middle-sized flowers in a calix.—Native of Dauphiny, on walls.

51. *Hieracium Albidum*. Leaves gnawn, ligulate, hispid; stem subdichotomous, few-flowered; root perennial, long, oblique, simple, woody; flowers large, reddish on the outside, pale yellow within; seeds short, brown, crowned by a sessile egret of simple hairs, but toothed and russet: the whole plant is rough, of a yellowish green, and covered with glandular hairs, that give it a disagreeable smell.—Native of sunny pastures, on the high mountains of Dauphiny and Savoy.

52. *Hieracium Pappolencon*. Leaves lyrate, spatulate, toothed; stem-leaves with two ears embracing the stem on both sides; stem striated, viscid, two-flowered, a foot long, firm, thick; root perennial, simple, thick, dividing at top into two parts, one of which produces a stem without leaves at the base, and the other a bundle of root-leaves without stem for the most part; the stem is terminated by one, two, three, and even as far as fourteen pretty large flowers, which are all on separate peduncles.—Native of Dauphiny, where it is found in Alpine meadows.

53. *Hieracium Florentinum*. Stem brachiate, few-flowered; leaves lanceolate, long-haired; calices smooth. This plant is about a foot high, with an upright stem, not putting out runners; calix very smooth; flowers small, heaped on the top of the stem; perennial.—Native of Switzerland, the Valais, and Piedmont.

54. *Hieracium Capillacium*. Stem almost naked, one-flowered; leaves nerved, grassy, quite entire; root thick-black, perennial; scape a hand in height, almost naked, simple, one-flowered.—Native of the county of Nice, about Sospel.

55. *Hieracium Succisæfolium*. Leaves smooth, quite entire; root-leaves elliptic, on long petioles; stem-leaves clasping, with blunt hooks; root perennial; calix black and hairy.—Native of Switzerland and Piedmont.

High Taper. See *Verbascum*.

Hillia; (so named in honour of Sir John Hill, M. D.) a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth double, lower six-leaved; leaflets opposite, unequal, oblong, entire, the two inner smaller, embracing the germen, deciduous, coloured; upper two to four-leaved; leaflets lanceolate, acute, erect, permanent. *Corolla*: monopetalous; tube cylindric, very long, striated, towards the border ventricose; border six-cleft; clefts long, reflex, contorted, revolute. *Stamina*: filamenta six, very short, inserted below the border into the belly of the tube; antheræ oblong, two-celled, within the throat of the corolla. *Pistil*: germen inferior, oblong, obscurely six-cornered; style filiform, thick, the length of the tube; stigma thickened, compressed, bifid. *Pericarp*: capsule elongated, angular, two-celled, opening longitudinally into two valves, crowned with the leaflets of the upper calix. *Seeds*: numerous, pappose, round a linear receptacle; down capillary. *Observe*. The second species takes away a sixth and a fifth part of the number. **ESSENTIAL CHARACTER.** *Calix*: double, lower six-leaved. *Corolla*: very long, contorted. *Capsule*: two-celled, two-valved, crowned. *Seeds*: downy.—The species are.

1. *Hillia Longiflora*. Corollas six-cleft, clefts lanceolate, revolute; leaves ovate, acute. This is a shrub with an ascending stem; a fathom in height, branched, loose, smooth, brittle, covered with an ash-coloured, shining bark; branches simple, leafy, round, smooth, brittle; flowers terminating, sessile, solitary, very long, white, very sweet.—Native of Jamaica and Martinico, in wet coppices upon the mountains. It is not parasitical, but creeps among old mossy wood; flowering in summer.

2. *Hillia Tetrandra*. Corollas four-cleft, four-stamined; clefts ovate; leaves obovate. This shrub is a native of Jamaica.

Hippia. A genus of the class Syngenesia; order Polygamia Necessaria. *Calix*: common, hemispherical, somewhat imbricate, with ovate scales. *Corolla*: compound, discoid; floscules male, several in the disk; females ten in the circumference, proper of the males funnel-form, five-cleft, upright; of the females obsolete, tubulous, two or three-cleft.

Stamina: in the males, filamenta five, very short; antheræ cylindric, shorter. *Pistil*: in the females, germen margined, large; style bifid; stigmas upright. *Pericarp*: none; calix unchanged. *Seeds*: in the females oval, with a very wide rim all round, naked. *Receptacle*: naked. **ESSENTIAL CHARACTER.** *Calix*: hemispherical, subimbricate. *Corollas* of the ray ten, obsolete, subtrifid. *Seeds*: with very broad margins, naked. *Down*: none. *Receptacle*: naked. —The species are,

1. *Hippia Integrifolia*; *Annual Hippia*. Hispid, erect: leaves ovate, serrate, five-nerved; racemes terminating. —Native of the East Indies.

2. *Hippia Minuta*; *Minute Hippia*. Herbaceous, procumbent, creeping, smooth: leaves pinnate; peduncles axillary, one-flowered; stems procumbent, jointed, putting out rooting fibres at every joint; flowers small. —Native of South America.

3. *Hippia Frutescens*; *Shrubby Hippia*. Shrubby, villose: leaves pinnatifid; flowers corymbed; stem shrubby, eight or ten feet high, sending out branches on every side the whole length. The flowers are produced in small roundish bunches at the ends of the branches: they are of a sulphur colour, and appear in May. There is a succession of flowers on the same plant during great part of the summer. The seeds of this plant rarely ripen in England; but it is easily propagated by cuttings planted in a bed of loamy earth, during any of the summer months. Shade them from the sun until they have taken root, and refresh them frequently with water; take them up with balls of earth about their roots, plant them in pots, and place them in a shady situation until they have taken new root, then remove them to a sheltered place among other hardy exotics, and in October put them into shelter. This plant requiring only protection from frost, must not be too tenderly treated.

Hippocratea: a genus of the class Triandria, order Monogynia. —**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-parted, very small; leaflets roundish, spreading, incumbent, smaller than the corolla. *Corolla*: petals five, ovate, spreading, permanent, excavated at the tip, villose. *Stamina*: filamenta three, contiguous to the germen and style, awl-shaped, reflex at the tip; antheræ roundish, with a transverse groove. *Pistil*: germen roundish; style three-sided, awl-shaped, longer than the stamina; stigma blunt. *Pericarp*: capsules three, obcordate or elliptic, compressed, large, with two-valved cells; valves keeled and compressed. *Seeds*: in fives or sixes, oblong, with a membranaceous wing, at first soft, but afterwards hardening like nuts, with oblong kernels. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Petals*: five. *Capsule*: three, obcordate or elliptic. —The species are,

1. *Hippocratea Volubilis*. Racemed, corymbed: leaves ovate, lanceolate, serrate. This is a scandent and not a climbing plant, growing to the height of eight or ten feet, with very slender stalks; flowers terminating, subsessile, crowded, greenish white, minute. —Native of Carthage in New Spain, and several of the West India islands. Swartz says it flowers in the spring; Jacquin saw it flowering both in April and December, and gathered the fruit in July. He informs us, that in the dry season, when all the trees lose their leaves, this plant, with the Capers and a few others, continue flourishing. It is propagated by seeds brought from South America and the West Indies. Jacquin informs us that they corrupt very soon, and that therefore we can hardly expect to raise plants from seeds sent to Europe: if so, they should be sown whilst fresh, and sent over in pots or tubs. Mr. Miller however raised several plants from seeds, which

lived two years, but did not flower: he thinks that they were rotted by having too much wet, and recommended the giving them little water in winter. They are very tender, and must be kept constantly in the bark-bed in the stove.

2. *Hippocratea Comosa*. Panicles comose; peduncles multifid, capillary; leaves ovate, acuminate, entire. —Native of Hispaniola.

Hippocrepis: a genus of the class Diadelphia, order Decandria. —**GENERIC CHARACTER.** *Calix*: umbel simple; perianth one-leaved, five-toothed (the upper toothlets joined, and less divided,) permanent. *Corolla*: papilionaceous; banner heart-shaped, with a claw the length of the calix; wings ovate, oblong, blunt; keel lunulate, compressed. *Stamina*: filamenta diadelphous (simple and nine-cleft,) ascending; antheræ simple. *Pistil*: germen slender, oblong, ending in a subulate ascending style; stigma very simple. *Pericarp*: legume compressed and membranaceous, very long, curved inwards, one of the sutures many times cut almost to the top into roundish sinuses, and hence consisting of several joints obtusely triangular, connected by the upper suture. *Seeds*: solitary in each joint, oblong, incurved. *Observe.* The essential character consists in the horse-shoe form of the legume. **ESSENTIAL CHARACTER.** *Legume*: compressed, several times emarginate along one of the sutures, curved. These plants are propagated by seed, which should be sown in the autumn wherever the plants are intended to remain; when they come up, weed them, and thin them where too close, which is all the culture they require. —The species are,

1. *Hippocrepis Unisiliquosa*; *Single-podded Horse-shoe Vetch*. Legumes sessile, solitary, straight. This is an annual plant, which sends from the root several trailing stalks a foot long, that divide upwards into smaller branches. From the wings of the stalk come out single flowers, which are yellow, and are succeeded by single pods sitting close to the stalks, which are about two inches long, and a third of an inch broad, bending inwards like a sickle, and divided into many joints, shaped like a horse-shoe. This flowers in June and July, and ripens seed in autumn, soon after which it decays. Observed by Ray near Leghorn and Naples. —Native of Italy, and the south of Europe.

2. *Hippocrepis Multisiliquosa*; *Many-podded Horse-shoe Vetch*. Legumes peduncled, crowded, circular, smooth, lobed on the outer margin; leaves and calices smooth: the trailing stalks of this plant, bear a great resemblance to those of the preceding, but its flowers are produced on long axillary peduncles. They are small, yellow, and many clustered together. Native of the south of Europe. Like the preceding, it is annual, and decays in autumn after the seeds are perfected.

3. *Hippocrepis Balearica*; *Shrubby Horse-shoe Vetch*. Legumes peduncled, crowded, smooth, lobed on the outer margin; leaves and calices somewhat hairy; stems ancipital; root short, woody, the thickness of a finger: the flowers have a small degree of sweetness; corolla yellow. It flowers in May and June. —Native of Minorca. The roots will last two or three years in good ground in a green-house.

4. *Hippocrepis Comosa*; *Tufted Horse-shoe Vetch*. Legumes peduncled, crowded, arched, rugged, sinuated on both margins; root perennial, thick, woody, fibrous, yellow on the outside, white within. The whole plant is smooth; stems trailing, ascending, grooved, from two to nine inches long, much branched; peduncles axillary, round, grooved, from two to five inches long, two or three from the upper axils, and one terminating; flowers six to eight or ten, disposed in a circle round the top of the peduncle, after flower-

ing, bent down; corolla yellow. The Germans call this plant *Hufeisenpflanze*; the Dutch, *Hoefzyfer*; the Danes, *Hestesko*; the Swedes, *Hatsko*; the French, *Fer à Cheval*; the Italians, *Ferro di Cavallo*; the Spaniards, *Hierba de la Herradura*, *Herradura de Caballo*; and the Portuguese, *Ferradurina*, *Esferro Cavallo*. It flowers from April to May, and is found in the calcareous soils of Germany, Italy, France, Austria, and England.

5. *Hippocrepis Barbata*; *Bearded Horse-shoe Vetch*. Legumes straight; spike oblong, terminating; stem suffruticose, four feet high, upright, round; flower purple, terminating in an oblong dense spike.—Native of Cochinchina. It has not yet been introduced into the gardens of Europe.

Hippomane; a genus of the class Monœcia, order Monadelphica.—GENERIC CHARACTER. *Male Flowers*: in a terminating ament. *Calix*: perianth one-leafed, roundish, bellying, with the mouth converging, emarginate. *Corolla*: none. *Stamina*: filamenta single, filiform, twice as long as the calix; antheræ four, roundish, fixed crosswise to the sides of the filamentum towards the tip. *Female Flower*: terminating, solitary, in the same plant. *Calix*: perianth three-leaved, withering; leaflets roundish, concave, blunt, converging. *Corolla*: none. *Pistil*: germen ovate, large; style very short; stigma slightly seven-cleft, sharp, reflex. *Pericarp*: drupe globular, very large, one-celled, crowned with the permanent stigmas, or a tricoecous capsule. *Seed*: nut woody, irregular, acuminate, excavated with little pits and apophyses, seven-celled, seven-valved; kernels solitary, roundish. ESSENTIAL CHARACTER. *Male Ament*. *Perianth*: bifid. *Corolla*: none. *Female*. *Perianth*: trifid. *Corolla*: none. *Stigma*: three-parted; drupe or capsule three-grained. These plants can never be expected to rise to any great height in Europe, though in the stoves they may be easily raised from good seeds. They must be sown upon a hot-bed, and when the plants come up, they should be each planted in a small separate pot filled with light sandy earth, and plunged into a good bed of tanner's bark. They require the same treatment as other tender plants; but must not have much wet, for they abound with an acrid milky juice, and it is certain that most plants which do, are soon killed by such moisture. These plants must be removed into the stove and plunged into the tan-bed in autumn, where they may be suffered to remain in winter, giving them very little water, and plenty of air in summer, when they may be watered once a week: this management may raise them to the height of five or six feet, and their green shining leaves form a pleasing variety during winter in the stove.—The species are,

1. *Hippomane Mancinella*; *Manchineel Tree*. Leaves ovate, serrate, biglandular at the base. The trunk is of a middling size, with a gray, even, thick, milky bark, and a hard wood, which is yellowish, with gray or blackish veins; flowers in aments or spikes; fruit a drupe, the colour, size, and form of an apple, smooth, with a soft spongy flesh, a sweet smell, and an insipid caustic taste. Within is a nut from three to five cells, with a single seed in each, which is three-cornered, covered with a shining silvery skin, and having the taste of a hazel-nut. Mr. Miller describes the fruit as about the size and shape of the Golden Pippin, turning yellow when ripe. The European nations have, with little variation, given it the Spanish name of *Mancanilla*, or little apple. It drops from the tree in great quantities, not rotting but drying up, and does not seem to be eaten by any animal, except perhaps by a species of crab, which resorts to these trees in incredible quantities, but probably rather for shelter than for food. Dr. Patrick Browne informs us that he has known many people who have ignorantly eat of this fruit,

which they had mistaken for crab-apples: they generally vomited in a short time, and continued to complain of a burning heat in the mouth, throat, and stomach, for many hours after. The juice of the buds of the white Cedar is esteemed an antidote to this poison, and is generally used with some success; but oily mixtures and emulsions are the most effectual assistants, and seldom fail to afford relief. He adds, that he has never known any to die by this poison, though he has seen some who have eaten nine or ten of the apples at a time. Long says, that though the green fruit may be destructive in considerable quantities, yet small quantities may be taken without danger, as it is too disagreeable from its acrimony to excite any desire of eating much; and even when ripe, is too insipid to raise any pleasure; though goats, sheep, and macaws feed greedily upon it in that state. The first accounts of this tree were very much exaggerated. It was said to be dangerous to sit or lie under it, and that the rain which falls from the leaves will raise blisters in the skin. Professor Jacquin informs us that he and his companions reposed upwards of three hours under a Manchineel-tree, without receiving any injury, and that he experienced rain dropping from the leaves to be perfectly innocent. Long also says, that the negroes do not suffer any inconvenience from drops of the juice accidentally falling on their skin when felling this tree, or hacking off the limbs; but if it chance to fly into their eyes, it will give them a severe pain for several hours: and Jacquin likewise acknowledges, that a drop of that milky juice with which the whole tree abounds, falling on any part of the hand, except the palm, will immediately raise a blister. The wood of this tree is frequently of a fine grain, and very beautifully clouded. It will take a fine polish, and being very durable, and not subject to be eaten by the worm, it is much esteemed in the West Indies for making cabinets, bookcases, &c. The wood-cutters are said to make a fire round the body of the tree before they venture to fell it, to avoid the danger of losing their sight by the caustic juice flying into their eyes. If the juice fall upon linen, it will turn black; and when washed, fall into holes. The carpenters generally cover their faces while working at this wood, for if any of the saw-dust get into their eyes, it generally produces an inflammation. The Indians are said to poison their arrows with the juice of this tree, and it exudes a gum which has been given medicinally instead of gum guaiacum. The Manchineel-tree is common on the sandy coasts of America and the West Indies, generally growing at some small distance from the surf. It flowers in May, and the fruit ripens in July. In the West Indies this tree almost equals the Oak in size. Jacquin says it is a lofty large tree, with a very branching spreading head, having something of the air of a Pear-tree.

2. *Hippomane Biglandulosa*; *Gum Tree*. Leaves ovate, oblong, biglandular at the base. This tree is from twenty to fifty feet high, with an even, brownish, ash-coloured bark; spikes terminating and lateral, clustered, rather to be called aments. A single ament of male flowers, at the beginning of the flowering time, springs among other small ones, flowers, and falls: thick scales like glands cover the ament, commonly a pair opposite to another pair, ovate, thick, pressed close, adnate; perianth from the sinus of two scales, tubular, irregularly four-cleft, blood-red. The whole tree contains a great quantity of milky juice, which becomes a resin or gum of a thick sticky consistence, dirty colour, opaque, and of little or no smell: this generally serves for the boiling house-lamps, in every part of the country where the tree is frequent, and is much used for birdlime. The wood is soft and coarse, and not much esteemed; it is used however for making hogshhead staves. The flowers appear in March and September.—Native

of mountains on the continent of America, and in the West India Islands: found also in New Spain.

3. *Hippomane Spinosa*. Leaves subovate; tooth spiny. This is seldom more than twenty feet high. Found at Campeachy.—Native of South America.

Hippophae; a genus of the class Diœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male Calix*: perianth one-leaved, two-parted, two-valved, with the bottom entire: the parts roundish, blunt, concave, upright, converging at the tips, and gaping on the sides. *Corolla*: none. *Stamina*: filamenta four, very short; antheræ oblong, angular, almost the length of the calix. *Female Calix*: perianth one-leaved, ovate-oblong, tubular, club-shaped, with the mouth cloven, deciduous. *Corolla*: none. *Pistil*: germen roundish, small; style simple, very short; stigma thickish, oblong, upright, twice as long as the calix. *Pericarp*: berry superior, subglobular, one-celled. *Seeds*: single, oblong, hard, shining. *Observe*. Hermaphrodite flowers have sometimes been observed among the males. **ESSENTIAL CHARACTER.** *Male Calix*: two-parted. *Corolla*: none. *Female Calix*: bifid. *Corolla*: none; style one. *Berry*: one-seeded.—These plants may be easily propagated by suckers from the root, taken off in autumn, and transplanted into a nursery. After one year's growth they will be fit to transplant where they are to remain. They may also be increased by layers, but the roots spread, and put up such abundance of suckers, that there is no necessity to be at this trouble. There being little beauty in these shrubs, it will be sufficient to have one or two of them in plantations.—The species are,

1. *Hippophae Rhamnoides*; *Common Sea-Buckthorn*, or *Sallow Thorn*. Leaves lanceolate. It rises with shrubby stalks eight or ten feet high, sending out many irregular branches, which have a brown bark silvered over. The branches spread wide, are straight, stiff, and thorny at the ends, the lesser ones numerous, scattered, short, and spreading; flowers solitary, appearing before the leaves, generally abortive, unless the shrub grows in its natural situation. The female flowers are sessile in the axils of the lower leaves: the male flowers are subsessile, somewhat spiked, disposed in four rows along the lesser branches. The flowers come out from the branchlets of the former year. The berries are very abundant, gratefully acid, and much eaten by the Tartars. They are the principal food of peasants upon Mount Caucasus. The fishermen of the Gulf of Bothnia prepare a rob from them, which imparts a grateful flavour to fresh fish. In sunny situations this shrub is planted for hedges, and is used for dyeing yellow. Cows refuse it; goats, sheep, and horses use it. It varies with red berries. Miller says, that he has observed it only with yellow berries in England, but that he had seen it on the sand-banks in Holland with red berries. The Germans call it *Haftdorn*; the Dutch, *Duinbessen*; the Swedes and Danes, *Haftorn*; the French, *Argoussier*; the Spaniards, *Espino Amarillo*; the Russians, *Rakitnik*. It flowers in April and May; Ray says in June, and Miller in July.—Native of many parts of Europe, on sandy sea-coasts. In England it is found near Sandwich, Deal, Folkstone, and the isle of Shepey in Kent, on Canvey Island in Essex; upon Cley and Sberingham cliffs, and between Yarmouth and Winterton in Norfolk; in Lincolnshire; and at Whitby and Lyth in Yorkshire.

2. *Hippophae Canadensis*; *Canadian Sea Buckthorn*. Leaves ovate. This has the appearance of the preceding species, but the leaves are broader and only half the length, the branches are opposite, and the racemes simple among the first leaves, upright, and shorter by half than the leaves.—Native of Canada.

3. *Hippophae Argentea*. Leaves ovate, obtuse, glabrous on both sides. This shrub resembles *Eleagnus Orientalis* so much that they might easily be mistaken for each other when without fruit: but this species bears really a berry different from the drupe of the other genus.—Found by Mr. Lewis on the banks of the Missouri. Mr. T. Nuttall, who has recently travelled through various parts of North America, and is as skilful as he is indefatigable in botanical researches, has added to the specific description of this plant given by Lewis, the important particular, that the blossoms are all four-cleft.

Hippuris; a genus of the class Monandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: a two-lobed rim, crowning the germen. *Corolla*: none. *Stamina*: filamentum one, upright, placed within the anterior lobe of the calix; antheræ roundish, compressed. *Pistil*: germen oblong, inferior; style one, awl-shaped, upright, from the hinder lobe of the calix, longer than the stamen; stigma sharp. *Pericarp*: none. *Seed*: one, roundish, naked. **ESSENTIAL CHARACTER.** *Calix*: a two-lobed rim to the germen. *Corolla*: none. *Stigma*: simple. *Seed*: one.—The species are,

1. *Hippuris Vulgaris*; *Common Mare's Tail*. Leaves eight at a joint, awl-shaped; root perennial, creeping, white-jointed; the joints furnished with numerous capillary fibres; stems numerous, a foot and half or more in height, upright, quite simple, smooth, striated, round, jointed, spongy; the pith like a thread in the centre, compact, and in the roots tough; flowers axillary, sessile, one to each leaf in the whorls that are above water. Linneus remarks, that the flower of this plant is as simple as can be conceived, having neither calix nor corolla, only a single stamen and pistil, and one seed. The situation also of the leaves is not usual in European plants, they are in whorls. Whilst several botanists are discarding the class Gynandria from the system, Retziers desires to remove this plant from the class Monandria into it, on account of the stamina being placed upon the germen. At the beginning of the summer the flowers are mostly hermaphrodite, but at the close of it many of them are female. Gerarde calls this plant, *Female Horse-tail*, and Parkinson *Marsh Barren Horse-tail*: Mr. Hudson first named it *Mare's-tail*. The French call it *Pesse d'Eau*, a translation of one of its old names *Limnopeuce* or *Water Pine*. The Germans call it, *Schafthalm*, *Tannen-wedel*; the Dutch, *Kattestaart*, *Paardestaart*; the Danes, *Hesterumpe*, *Van-Studeknæ*; the Swedes, *Hastvans*; and the Italians, *Hippuride*;—Native of many parts of Europe, in ponds, ditches, marshes and rivers, especially where there is a depth of mud, and the frost cannot reach the roots. In quiet waters it grows upright, in running waters it bends with the stream, and in large lakes rises to the height of several feet. In some countries it is a troublesome weed in rivers, and choaks up the ditches; but by absorbing a great quantity of inflammable air, it is reputed to assist in purifying the putrid air of marshes. Gmelin says, that the wild ducks in the north feed upon it. Goats are also said to eat it. We do not know that it is of any other use. It flowers from May to August, and is not very common in England, though found in several parts of Cambridgeshire, Oxfordshire, Westmoreland, Staffordshire, Leicestershire. Near London it is more rare: Blackstone found it in Harefield river, and upon Uxbridge moor; Hudson, in the New River near Hornsey; and Dr. Milne, near Stoke Newington and Highgate.

2. *Hippuris Tetrphylla*; *Four-leaved Mare's Tail*. Leaves four at a joint, oblong, blunt. This is always very distinct from the preceding, by its only having four leaves on a whorl, and their being spatulate-ovate and blunt. It has the appearance of *Elatine Alsinastrum*, and is clearly a gynandrous

plant.—Native of Sweden, first discovered by Schulsen, near Abo in Finland.

3. *Hippuris Indica*; *Indian Mare's Tail*. Scape naked; root tuberous. This is a stemless plant, with a fibrous creeping root, having many roundish, scattered, small, black, hairy tubers, which are eatable.—Native of the marshes of Cochinchina.

Hip Tree. See *Rosa Canina*.

Hiræa; a genus of the class Decandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets ovate, upright, very small, permanent. *Corolla*: petals five, roundish, concave, with long claws. *Stamina*: filamenta ten, capillary, united at the base, the outer ones shorter; antheræ roundish, upright. *Pistil*: germen roundish; styles three, simple, upright; stigmas bifid, blunt, spreading. *Pericarp*: capsules three, upright, keeled on the back; each having a single spreading wing on the outside at the base, and a double one at the tip, not gaping. *Seeds*: solitary, roundish. *Observe*. Too nearly allied to *Triopteris*: differing in having three two-winged capsules, instead of a three-celled capsule with three wings. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: roundish, on long claws. *Capsule*: three-celled, with three wings, according to Jacquin, three with two wings one-celled. *Seeds*: two. Jacquin says, solitary.—The only known species is,

1. *Hiræa Reclinata*. This is a small tree, seldom exceeding fifteen feet in height, and dividing into round, long, smooth, bending and reclining branches, by which it supports itself on neighbouring shrubs. Bark ash-coloured; leaves oblong, a little broader at top, blunt at both ends, quite entire, smooth underneath, having soft, decumbent, scarcely conspicuous hairs on the upper surface, and being from three to six inches long; the petiole has two upright bristly stipules at the base. Common peduncles thick, very short, and numerous, beautifully surrounding entire and very long branches, and by means of twelve semioval short bractes, finish in a quadrilocular top; the partial peduncles being one-flowered, an inch long, solitary, and therefore four to each common peduncle. Flowers beautiful, but without scent, yellow, an inch in diameter.—Native of woods in Carthage, New Spain, flowering in June, and ripening seeds in September.

Hirtella; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-parted; parts subovate, reflex, unequal, permanent. *Corolla*: petals five, roundish, concave. *Stamina*: filamenta three or five, bristle-shaped, flattish, very long, permanent at length, rolled in spirally; antheræ orbiculate. *Pistil*: germen roundish, compressed, and declining, villose; style filiform, almost the length of the stamina, arising from the depressed side of the germen; stigma simple. *Pericarp*: berry oval, broader at top, a little compressed, obscurely three-cornered, at whose base in front lie a villose germen and style. *Seed*: one, large, of the same form with the pericarp. **ESSENTIAL CHARACTER.** *Petals*: five. *Filamenta*: very long, permanent, spiral. *Style*: lateral. *Berry*: one-seeded.—The species are,

1. *Hirtella Americana*. Leaves ovate, lanceolate; branchlets hirsute; racemes upright, simple; flowers five-stamined. This is a tree with a trunk from twenty-five to thirty feet in height, and a ferruginous bark; petals rounded, with claws emarginate, bluish; germen rounded, villose; berry obovate, compressed, hairy, rough, dry.—Native of Cayenne, where the French call it *Bois de Goulette*.

2. *Hirtella Triandra*. Leaves oblong, acuminate; racemes compound, loose; flowers three-stamined. This is a branching tree, which sometimes rises twenty feet high, but is gene-

rally less. The flowers have no scent; the stamina and style are placed cross-wise. The calicine segments are ovate, roundish, concave, equal, reflex; petals spreading, equal, deciduous, white; stigma simple. It flowers in April and May, and is found in Jamaica, Martinico, and San Domingo.

3. *Hirtella Paniculata*. Leaves elliptic, shining, with hairy, subcoriaceous racemes, upright; flowers five-stamined; branches round, with a purplish bark, rough-haired at top; stipules awl-shaped, very rough-haired; pedicels copious, alternate, solitary, or sometimes, but seldom, two together; bractes ovate, frequently two on the pedicel, hirsute on the outside, and others lanceolate at the base of the pedicel; filamenta five, long; style hirsute at the base.—Native of Cayenne.

Hoeing, is beneficial to plants: first, for destroying weeds; secondly, because it disposes the ground better to imbibe the night dews, keeps it in a constant freshness, and adds a vigour to the plants and trees, by which their fruit becomes more abundant, as well as more nutritious. This operation is performed by the hand. Of the instrument called a Hoe, (and well known to every gardener,) there are several sizes. The smallest, called an Onion Hoe, is used not only to cut up young weeds, but to thin the Onions, by removing all such as are too close. The next size is nearly four inches and a half broad, and is called a Carrot Hoe, from being used for carrots, and any other crops where the same distance is required to be left between the plants. The largest size is about seven inches broad, and is frequently called a Turnip Hoe, from its being used in hoeing Turnips, but which is generally employed by the Kitchen gardeners for hoeing between all their crops which are planted out, or stand so far asunder as to admit an instrument of this breadth to pass between the plants. Besides, these sorts of hoes, which are contrived to draw *towards* the person who uses them, there is another of a different form, which is called a Dutch Hoe, designed to be pushed *from* the person using it, so that he does not tread over the ground which is hoed. This is a very proper instrument for scuffling over the ground to destroy weeds, whenever the plants will admit of its being used; and a person will go over a much greater space of ground with one of these instruments, than with the common hoe; but they are not so proper for hoeing our crops so as to leave the plants at a proper distance, nor will it penetrate the ground so far; therefore the other sort of hoe is to be preferred to this, because it stirs the ground and loosens the surface, thereby promoting the growth of the plants. There has been of late years another instrument introduced into the field culture, called the Horse Hoe, which is a sort of plough with the share set more horizontally than that of the common plough. The utility of Horse-hoeing is first in proportioning the number of plants which the ground is supposed to be capable of nourishing. The second is, that by frequently stirring the surface of the land, all weeds which rob the crop of its nourishment are destroyed, and the clods of earth divided and pulverized, so that the roots of the plants can more easily penetrate them, and search their proper food; besides, the dew and moisture are easily imbibed in the loose ground, whereby the plants receive a greater share of nourishment. There are few persons who properly consider of what consequence the stirring and breaking of the ground is to all crops growing therein. It has frequently been tried, when the crop has been so bad as to be thought not worth standing, which has been occasioned by the great quantity of rain binding the surface of the ground so closely that the plants could find no nourishment, but have changed from their usual verdure to a purple colour, and made no progress; yet when the clods have been broken and the ground hoed, they have put forth new roots

and flourished exceedingly. From many repeated trials of this kind, it is evident that if the wheat in general were sown in rows, so that the plough might be brought between the rows in the spring, to loosen the ground, which by the winter's rains may have been too closely bound, the crop would more than double what is the common produce. And by this method of husbandry we can affirm that all crops will be so much improved, as doubly to repay the difference of expense, while less than a sixth part of the seed will be enough for the same ground. The common swing plough answers all the ends of Horse-hoeing.

Hoffmannia; a genus of the class Tetrandia, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, four-toothed, superior; teeth upright, sharp. *Corolla*: monopetalous, salver-shaped; tube so short as to be next to none; border four-parted; parts lanceolate, spreading. *Stamina*: filamenta none; antheræ four, fixed to the base of the tube, linear-subulate, upright, pressed close to the style. *Pistil*: germen inferior, oblong, four-cornered; style subulate, the length of the stamina; stigma blunt, scarcely emarginate. *Pericarp*: berry oblong, slightly four-cornered, crowned, two-celled, two-valved. *Seeds*: numerous, roundish, fixed to receptacles in each cell. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Corolla*: salver-shaped, four-parted. *Filamenta*: none. *Berry*: two-celled, many-seeded.—The only known species is,

1. *Hoffmannia Pedunculata*.—Native of Jamaica; found there by Swartz.

Hog Plum. See *Spondias*.

Hog's-Fennel. See *Peucedanum*.

Hog-weed. See *Boerhavia*, *Heracleum Sphondylium*, and *Polygonum Aviculare*.

Holcus; a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** *Hermaphrodite Flowers*: sessile. *Calix*: glume one-flowered, two-valved, subovate, obtuse, coriaceous, awnless; outer valve large, concave, slightly three-toothed at the tip, embracing the inner valve, which is oblong, rolled up on the sides. *Corolla*: glume two-valved, tender, villose, less than the calix; outer valve smallest, placed within the inner calicine valve, in most of the species bifid at the tip and awned; awn from the cleft of the glume, long or short, jointed, twisted, sometimes none; nectary three-leaved, two of the leaflets cartilaginous, truncate, the third opposite, ovate or lanceolate, villose. *Stamina*: filamenta three, capillary, very tender; antheræ oblong, bifid. *Pistil*: germen ovate; styles two, capillary, diverging; stigmas oblong, feathered. *Pericarp*: none, but the glumes of the corolla and calix are rolled about the seed, and inclose it. *Seed*: solitary, ovate, covered, armed with the awn of the corolla, which however easily falls off. *Male Flowers*: peduncled, solitary, or in pairs, accompanying the hermaphrodite, smaller. *Calix*: glume two-valved; valves ovate-lanceolate, sharpish, chaffy, awnless; the outer valve concave, embracing the inner, which is narrower. *Corolla*: glume two-valved, smaller, more tender; outer valve within the inner valves of the calix, shorter, two-toothed, awnless; the inner valve doubled upon the edges; nectary as in the hermaphrodites. *Stamina*: filamenta three, as in the hermaphrodites. *Pistil*: germen small, angular, abortive; styles two, bristle-shaped; stigmas none. **ESSENTIAL CHARACTER.** *Hermaphrodite Calix*: glume one or two-flowered. *Corolla*: glume awned. *Stamina*: three. *Styles*: two. *Seed*: one. *Male Calix*: glume two-valved. *Corolla*: none. *Stamina*: three.—The species are,

1. *Holcus Spicatus*; *Spiked Holcus*. Glumes two-flowered, awnless; flowers in pairs, involucred with a pencil;

spike ovate-oblong; culm two feet high, and about the thickness of a swan's quill. Annual; and a native of the East Indies.

2. *Holcus Bicolor*; *Two-coloured Holcus*. Glumes smooth, black; seeds globular, white-awned. This is an annual grass, greatly resembling the next species, but still very distinct from it, by its black calices, and seeds of a snowy whiteness.—Native of Persia.

3. *Holcus Sorghum*; *Indian Holcus*, or *Millet*. Glumes villose; seed compressed, awned; panicle contracted, ovate, upright, but drooping as it ripens. There are several varieties of this species; the most remarkable is the red-seeded one cultivated among the Caffres. Of this, the calix when ripe is cartilaginous, pale chesnut-coloured, very smooth, shining, only half the length of the seed, which is naked, obovate, globular, much acuminate towards the base, red, not shining. Miller describes this and the sixth species together, and indeed they differ so little as scarcely to merit being considered as a distinct species. According to him, the stalks of these plants rise five or six feet high, are strong, reedy, and like those of the Maize or Turkey Wheat, but smaller. The leaves are long and broad, having a deep furrow through the centre, where the midrib is depressed on the upper surface, and is very prominent below. The leaves are two feet and a half long, and two inches broad in the middle, embracing the stalks with their base. The flowers come out in large panicles at the top of the stalks, resembling at first appearance the male spikes of the Turkey Wheat: these are succeeded by large roundish seeds, which are wrapped round with the chaff.—They are both natives of India, where the grain is much used to feed poultry, and is frequently sent to Europe for the same purpose. This is much cultivated in Arabia, and most parts of Asia Minor. It has been introduced into Italy, Spain, Switzerland, and some parts of Germany. In China, Cochinchina, and the West Indies, where it grows to the height of five or six feet or more, and is esteemed a hearty food for labourers, it is called Negro Guinea Corn. Its long awns or bristles defend it from the birds. In Arabia it is called *Dora* or *Durra*; the flour is very white, and they make good bread of it. The bread made from it in some parts of Italy and Portugal is however dark and coarse. In Tuscany it is chiefly used for feeding poultry and pigeons; and even swine, cattle, and horses. Cæsalpinus says, however, that cattle when fed upon the green herb are liable to swell and die, although they thrive on it when dried, in which state brushes are made of it in Italy, some of which Mr. Ray observed in the Venetian shops. The Germans call this plant, *Mohrhirse*, *Sorgsamen*, *Sorgsaat*, *Welsche Hirse*, and *Indische Hirse*; the Dutch, *Gewoon Zorghzaad*, *Negerkoorn*; the French, *Houque Sorgo*, *Grand Millet*; the Italians, *Saggina Sagginella*, *Sorgo*, *Melica*; the Spaniards, *Alcandia*, *Melca*; the Portuguese, *Millo Lorgo*; the Tartars, *Myssur*, *Suburge*; the Japanese, *Sioku*, *Kibi*; and the inhabitants of Guinea, *Guarnatt*. The autumns of England are seldom dry and warm enough to ripen the seeds well in the field. Those who propagate them should sow the seeds on a warm border, or upon a gentle hot-bed, in March; and when the plants come up, they should be thinned, and planted at the distance of a foot asunder in the rows, which should be at three feet distance. The culture after this is to keep the ground clear from weeds, and draw the earth up with a hoe to the stems of the plants; if the season prove warm, their panicles will appear in July, and the grain will ripen in September, except in bad seasons, when it is liable to fail. It is thought that if the seeds were procured from Germany, and Switzerland, (climates not very different from our own,) that

Sorghum might be advantageously cultivated upon some of the warmer soils of our island.

4. *Holcus Halepensis; Panicle Holcus.* Glumes smooth, hermaphrodite flowers awnless, female awned; culm smooth and even; panicle spreading, purple; awns white at the tip. To each female or hermaphrodite flower, there are two male flowers, which are pedicelled. The root is perennial, and increased by lateral runners, like the reed. Allioni says it grows wild near Turin, and other parts of Montserrat.—Native of Syria.

5. *Holcus Nitidus.* Glumes one-flowered, villose, all the flowers awnless; culm round, upright, with bearded joints; panicle upright; peduncles in a sort of whorl. It is smaller than the preceding in all its parts, but has the same habit.—Native of the East Indies.

6. *Holcus Saccharatus; Yellow-seeded Holcus.* Glumes villose, all the seeds awned; root biennial; panicle large, diffused. The male flowers scarcely open. The villosity of the calix is as inconstant as the colour, and is almost always lost in maturity; the colour generally changes to dark or black; these circumstances therefore are unfit to use for specific distinctions. This and the third species differ little in habit or any thing else, except the one having a naked, and the other an incrustated seed. Brown calls it Guinea Wheat, and says it had been lately introduced into Jamaica.—Native of the East Indies, and cultivated in China and Cochin-china. See the third species.

7. *Holcus Mollis; Soft Holcus, or Creeping Soft-grass.* Glumes two-flowered, almost naked; hermaphrodite, floret awnless; male with a knee-jointed awn: it resembles the next species. Mr. Curtis says it is usually a smaller plant, or, if it be as tall, that it has a much more scanty panicle; the spikelets have not that brilliant colour which marks those of *Lanatus* at their first appearance. This grass also rarely occurs, except in and about woods, and in hedges; whereas the *lanatus* is a very general grass in meadows. It flowers in July, and is a very troublesome weed with its creeping roots, especially in arable lands.

8. *Holcus Lanatus; Woolly Holcus, or Meadow Soft-grass.* Glumes two-flowered, villose; hermaphrodite, floret awnless, male with a recurved awn; root perennial, but not creeping; stems from two to three feet high, upright, round, pubescent, with three or four joints. The velvet-like softness of the whole plant, and the redness of the opening panicle, render this grass very conspicuous. It abounds in meadows, is frequent by road-sides, and sometimes grows on walls. It flowers in June and July. Haller speaks highly of this grass as food for cattle, but it is not at all esteemed among us. The seed however being easily collected, is sometimes sent to London in great quantities as pure grass-seed. Lightfoot says that the stalks are used for making ropes for fishing boats in the isle of Skye; but there are better grasses for this purpose. Young, in his *Annals*, says, that a gentleman's horses having been much disordered with a malady which caused an extraordinary discharge of urine, the hay on which they fed, being examined, was found to contain scarcely any other grass but this; and that on changing the hay, the distemper ceased. This fact however should be well ascertained, before the *Holcus Lanatus* is recommended as one of the most valuable kinds of meadow-grasses, as it is by Dr. Anderson; though, since he calls it *Creeping Soft-grass*, and talks of its running roots, he may mean the preceding species, which certainly is one of the vilest weeds in arable lands: on the other hand, Mr. Marshall, in his *Rural Economy of Yorkshire*, says that it is far from an eligible grass for cultivation, is now entirely exploded by judicious husbandmen, and has been sup-

planted by Ray-grass; the growers of the seed being the only persons who have profited by its cultivation, eighty bushels having been produced from an acre. It is known in Yorkshire by the name of *White Hay Seeds*. In his *Minutes of the Midland Counties*, he says it ranks high as a pasture plant, at least for cattle; that a piece which abounds in it to one half, is esteemed excellent for cheese, favourable to the rearing of young heifers, and the fattening of Scotch bullocks; and that cattle of all kinds fare well upon it, except horses. For the propagation of this and the preceding species, see *Grass*.

9. *Holcus Laxus.* Glumes two-flowered, smooth, awnless, acuminate; panicle crowded, oblong. This has the habit of *Aira Cærulea*; culms two feet high, narrow, somewhat nodding; peduncles usually two-flowered.—Native of Virginia and Canada. See *Grass*.

10. *Holcus Striatus.* Glumes two-flowered, striated, awnless, acuminate; panicle crowded, oblong.—Native of the marshes of Virginia. See *Grass*.

11. *Holcus Serratus.* Glumes two-flowered, pubescent, awnless; leaves serrate; root perennial, creeping, covered at top with sheaths of leaves in clusters; culms decumbent at bottom, branched, covered with the sheaths of leaves below, naked above, a foot high, even, quite simple, almost leafless. Found at the Cape of Good Hope. See *Grass*.

12. *Holcus Odoratus; Sweet-scented Holcus.* Glumes three-flowered, awnless, acuminate; hermaphrodite, flower two-stamined; roots perennial, jointed, creeping; culm three feet high, with few joints. This grass has a sweet smell, and is collected into bundles, to lay among clothes and linen; and is hung over beds in some countries, with a view to procure sleep.—Native of wet pastures in the colder parts of Europe, and also of Canada, and Siberia. See *Grass*.

13. *Holcus Redolens.* Glumes three-flowered; side florets, male awned, hairy at the edge; the middle one subhermaphrodite, awnless; culm upright, a foot high, smooth, sheathed; panicle patulous, with filiform pedicels; stamina three, fertile in the males, barren in the middle flower.—Native of Terra del Fuego. See *Grass*.

14. *Holcus Latifolius.* Glumes three-flowered, the first floret unarmed, two prickly at the edge; leaves subovate; culm even, scarcely a foot high.—Found in China. See *Grass*.

15. *Holcus Pertusus; Perforated Holcus.* Spikes digitate; glumes with the outer valve punched with a hole in the middle; culm jointed, even, ascending, branched, about a foot high. Native of the East Indies.—*Guinea Grass*, (so called from its having been originally introduced into the West Indies from the coast of Africa,) according to Browne, is a species of *Holcus*. The characters of it, he says, agree pretty well with those of *Panicum* in general, but the flowers commonly grow very luxuriant, and though often hermaphrodite, are generally observed to be male and female distinct, surrounded by separate involucre, and standing on distinct pedicels within the same calix. The blades of this grass when flourishing, appear not unlike those of wheat, only rather longer and broader; and the stalks during the first growth are also much like those of wheat, but they get weaker and less the oftener the grass is fed upon or cut, till at last it becomes a fine, rich, and entire swath. It appears capable of thriving in any situation, climate; or soil, and can bear the effects of dry or wet weather in a most remarkable manner. In wet weather it may be cut once in a fortnight, and sometimes oftener when the land is new or fertile. In dry weather it is as long before it withers, and when reduced to such a state as to seem totally destroyed, will revive in a few hours after a slight shower; so that when so little rain falls as to be of no service to common pastures, this will be fit for use in a

few weeks; and in some situations, not exposed to the sun, it will flourish from occasional dews only. When ready to feed, it is from six to eight feet high, but it is generally fed on or out when three or four. It seems to have reached all parts of the world, and to be every where esteemed for its great usefulness. In the West Indies it is cultivated by making the land perfectly bare, by hoeing, and then digging holes from three to five feet distance, according to the quality of the soil. The holes should be large, and deep enough to bury a few roots of the grass at a good depth. These roots are procured from a neighbouring nursery or field, and the grass being lopped within three or four inches, they are put into the holes, well covered with earth, and pressed down with the foot: care is taken to keep the plants free from weeds by repeated hoeings. The best months for planting, are April and May, for the grass will then seed in September and October, at which time it produces in abundance. The ground must be quite clean when the seed is ready to drop; and if the spaces between the roots are then stirred by the hoe, it will be found very beneficial. When the seed is all fallen, stock are turned in, to tread it into the ground, and feed upon the grass. In very rich and new land, the grass at first will grow so rank as to produce very thick stalks, which by running up the noses of the stock, will prevent them from eating it so close as they otherwise would. When, however, it is eaten as near the ground as possible, the remaining grass, with the roots which were planted, are dug out with the hoe, and burnt off. After this, the grass, if favourable rains come, will grow from the seed, and by covering the ground, in May following will be perfectly established for several years, according to the quality of the land, to be cut for hay, or to stand for pasture. Whenever the grass grows thin, holes may be opened in such places, and roots again planted to supply it: and by this attention, a field will scarcely ever be so totally worn out, as to require the labour of entirely replanting it at any one time. If a little care only be taken of this grass in its infancy, it will soon overcome all other grasses and weeds; and in ground full of stones and rocks, though planted at random, and at great distances, as the soil admits, it will spread itself about them in a few months, and at last entirely cover them. If the stalks of this grass be buried a few inches deep, each joint of it will take root, and grow luxuriantly; or it may be propagated directly from sowing the seed, the ground being previously prepared for that purpose; but the seed will lie many months in the ground before it makes its appearance. Some planters do not stock up the roots which are planted, when the grass has seeded; and others depend upon what they afford, by continually feeding or cutting the grass when at a certain height, without ever suffering it to seed.

Holosteum; a genus of the class Triandria, order Triginia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, permanent. *Corolla*: petals five, two-parted, blunt, equal. *Stamina*: filamenta three, filiform, shorter than the corolla; antheræ roundish. *Pistil*: germen roundish; styles three, filiform; stigmas bluntish. *Pericarp*: capsule one-celled, subcylindric, gaping at the tip. *Seeds*: very many, roundish. *Observe.* In the third species, the petals are subtrifid, less than the calix. In the fifth species the

petals are three or two-toothed; stamina three or five; styles three or four; capsule six-valved at the tip. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: five. *Capsule*: one-celled, subcylindrical, opening at top.—The species are,

1. *Holosteum Cordatum*; *Heart-leaved Holosteum*. Leaves subcordate; stems decumbent, creeping, somewhat rigid at bottom; peduncles lateral, elongated, ascending, seven-flowered, one in the middle, and three on each side, from a peduncle farther branched.—Native of Jamaica and Surinam. In the former it is common, and thrives very luxuriantly. Browne calls it the Larger American Chickweed, and says that it grows in tufts, and seldom rises above ten or twelve inches from the ground, that the smaller birds feed much upon the seeds, which are seldom put to any other use, except that large wads of the fresh plant, heated over a gentle fire, are sometimes applied to hard and painful swellings, in order to relax the parts, and dispose the obstructions to a resolution.

2. *Holosteum Diandrum*; *Two-stamined Holosteum*. Stems procumbent, very rigid; leaves roundish; flowers two-stamined. This plant is very small, seldom rising above six or seven inches from the ground.—Annual, and a native of Jamaica.

3. *Holosteum Succulentum*; *Succulent Holosteum*. Leaves elliptic, fleshy; petals white, subtrifid, smaller than the calix.—Native of New York.

4. *Holosteum Hirsutum*; *Hairy Holosteum*. Leaves orbiculate, hirsute.—Native of Malabar.

5. *Holosteum Umbellatum*; *Umbelled Holosteum*. Flowers umbelled; root annual, slender, a little branched, fibrous, running perpendicularly down; stems numerous, filiform, jointed, round, perfoliate, upright, from two or three, to six inches high, having mostly three joints; the space between the two lowest is smooth, the others for the most part viscous and hairy; calix never opening, marked at the base with black dots; petals white, but often tinged with white on the outside, converging, concealed within the calix, so that the tips only peep out. Villars makes two species of this: 1. smooth, with triandrous flowers; 2. hairy, with decandrous flowers. The first smooth, smaller, and greener; the second very villose, larger, ash coloured, green all over; the peduncles and calices not clammy as in the other, which is more common. Hudson and Withering place it among the *Cerastia*; whilst Swartz would remove the *Alsine Media*, or common Chickweed, into this genus. It is an annual plant, flowering in April and May.—Native of Spain, Italy, France, Germany, Switzerland, and England; where it was first noticed on the walls of Norwich, and also upon walls and banks in the neighbourhood: it has also been found near Bury in Suffolk.

Homalium; a genus of the class Polyandria, order Triginia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, six or seven-cleft; clefts ovate, lanceolate, sharp, spreading very much. *Corolla*: petals six or seven, ovate, flat, a little longer than the calix, spreading very much; nectary-glands six or seven, flat, alternate with the petals. *Stamina*: filamenta eighteen to twenty-eight, subulate, upright, the length of the corolla, of which three or four are inserted into the receptacle, among the glands before the base of the petals; antheræ roundish, small. *Pistil*: germen roundish, villose, immersed at the base of the calix; styles three, upright; stigmas simple. *Pericarp*: capsule woody, ovate, one-celled. *Seeds*: very many, and very small. **ESSENTIAL CHARACTER.** *Calix*: six or seven-parted. *Corolla*: six or seven-petalled. *Stamina*: twenty-one in three bodies. *Pericarp*: one-celled, many-seeded.—The species are,

1. *Homalium Racemosum*. Leaves serrate; racemes axillary, and terminating; flowers peduncled. This is a lofty branching tree, with the habit and leaves of Elm.—Native of Martinico and Jamaica.

2. *Homalium Racoubea*. Leaves toothed, coriaceous; racemes terminating; flowers subsessile. This is a shrub, with a trunk of about three or four feet high, and four or five inches in diameter; the bark is whitish; the branches tortuous and spreading, and seven or eight feet long. The flowers are borne on spikes springing from the bosoms of the upper leaves; they are sessile, and of a yellow colour.—Native of Guiana.

Honesty. See *Lunaria*.

Hone-wort. See *Sison*.

Honey-flower. See *Melianthus*.

Honeysuckle. See *Lonicera*.

Honeysuckle, French. See *Hedysarum*.

Honey-wort. See *Cerinthe*.

Hooded Milfoil. See *Utricularia*.

Hooded Willow-herb. See *Scutellaria*.

Hop. See *Lupulus*.

Hopea; a genus of the class Polyadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, five-cleft; clefts ovate, blunt, permanent. *Corolla*: petals five, oblong, concave, connected at the base by the intervention of the bunches of stamina. *Stamina*: filamenta very many, bristle-shaped, longer than the corolla, connected at the base in five bodies; antheræ quadrangular. *Pistil*: germen inferior, roundish; style gradually thickening, the length of the corolla, permanent; stigma thickish, obliquely depressed. *Pericarp*: drupe dry, oval, cylindric, gibbous, crowned with the calix. *Seed*: not smooth, three-celled, protracted by a blunt tip. *Observe*. Two cells of the nucleus are frequently abortive, and obliterated. It seems to have an affinity with *Styrax*. ESSENTIAL CHARACTER. *Calix*: five-cleft, superior. *Corolla*: five-petalled. *Stamina*: many, connected in five bodies. *Style*: one. *Drupe*: with a three-celled nut.—The only known species is,

1. *Hopea Tinctoria*. This is a tree, with alternate, petioled, simple, oblong, lanceolate, ovate, subserrate, shining, nerveless, sweet leaves. The peduncles burst forth from buds upon the topmost branchlets, eight or ten together, before the leaves, and are disposed in a very short spike, on very short one-flowered pedicels, clothed with small, concave, villous leaflets. The flowers are succeeded by subsessile fruits below the leaves, in a very short spike. It flowers early in the spring, and is then extremely sweet. The juice or decoction of the leaves will dye linen and silk of a bright yellow colour.—Native of Carolina.

Hop-horn Beam. See *Carpinus*.

Hops. See *Humulus*.

Hordeum: a genus of the class Triandria, order Digynia.—GENERIC CHARACTER. *Calix*: common receptacle lengthened into a spike; glume six-leaved, three-flowered; flowers sessile; leaflets distant, in pairs, linear, acuminate. *Corolla*: two-valved; lower valve bellying, angular, ovate-acuminate, longer than the calix, ending in a long awn; inner valve lanceolate, flat, smaller; nectary two-leaved; leaflets ovate, sharp, ciliate. *Stamina*: filamenta three, capillary, shorter than the corolla; antheræ oblong. *Pistil*: germen ovate-turbinate; styles two, villose, reflex; stigmas similar. *Pericarp*: none: the corolla grows round the seed, without opening. *Seed*: oblong, bellying, angular, acuminate to both ends, marked with a groove on one side, according to Gærtner. *Observe*. In some of the species all the three flowers contained in an involucre are hermaphrodite and fertile; in

others the side flowers are males, and the middle one only is fertile hermaphrodite. ESSENTIAL CHARACTER. *Calix*: lateral, two-valved, (valves narrow, acuminate, distant, altogether forming a six-leaved involucre,) one-flowered, by threes at each toothlet of the rachis.—The species are,

1. *Hordeum Vulgare*; *Spring Barley*. All the florets hermaphrodite and awned, in two very upright rows. The first sort is the common Spring Barley, which is principally cultivated in England; of which the farmers make two sorts, viz. the Common and Rath-ripe Barley, which are the same: for the Rath-ripe is only that which has been long cultivated upon warm gravelly lands. The seed of this, when sown in a cold or strong land, will the first year ripen near a fortnight earlier than the seeds taken from strong land, therefore the farmers in the vales generally purchase their seed barley from the warm land; for if saved in the vales two or three years, it will become full as late in ripening as the common barley of their own product; and the farmers on the warm lands are also obliged to procure their seed barley from the strong land, to prevent their grain from losing its bulk and fulness. This sort of barley is easily distinguished by the two orders of beards or awns, which stand erect; the chaff being also thinner than that of the second and fourth sorts, is esteemed better for malting.—The second description is rarely cultivated in the southern parts of England, but in the northern counties and in Scotland is generally sown, being much hardier than the other species, and will bear the cold. It has its grains disposed in six rows: the grain is large and plump, but it is not so good for malting, which is the reason for its not being cultivated in the southern parts of the island, where the other sorts thrive well, and are better adapted to that purpose.—The third sort is the Long-eared Barley, which is cultivated in many parts of England, and is an exceedingly good sort, though some farmers object to it because the long and heavy ears are more apt to lodge. This has the grains regularly ranged in a double row, lying over each other like tiles on a house, or the scales of fishes. The husk or chaff of this barley is also very thin, and is much esteemed for malting.—The fourth kind is generally called Sprat Barley: it has shorter and broader ears than any of the other sorts; the awns or beards are longer, and the grains are placed close together, and the awns being long, the birds cannot so easily get out the grain. This seldom grows so tall as the other species; and the straw being shorter and coarser, does not make very good fodder for cattle.—Having described the different sorts of grain produced by this species and its varieties, before we proceed to notice the cultivation of barley we shall first briefly notice its description, and slightly touch upon its history. In Spring Barley, the lower flowers are frequently imperfect. The spike is as it were distinct, though there are several rows. In all the flowers the two glumes or chaffs of the calix are shorter than the flower, awl-shaped, and end in a short awn or beard. The outer corolline chaff is much hollowed, with the sides folded in, the back ciliated, and the tip continued into an awn three inches in length: the inner chaff is awnless. It is not known where this or any other sort of grain grows wild. Cardan pretended that barley was a native of Athol in Scotland. Reidesel says the same of Sicily: and it has lately been affirmed to be found on the banks of Samara, a river of Tartary. Diodorus Siculus ascribes the first culture of barley to Osiris, who discovered it in a wild state. The ancients fed their horses with barley as we do with oats. It was eaten also in bread by the lower sort of people; and the gladiators were called *Hordearii* or *Barley-men*, from their feeding on this grain. Some of the southern parts of Europe annually produce two crops of barley: one sown in autumn,

and cut in May; and another sown in spring, and cut in autumn. In many places of the north of Europe it is called *Korn*, or Corn, exclusively, and is more cultivated because it ripens in less time than any other kind of grain. In Lapland fifty-eight days only, or about two months, elapse between the sowing and the cutting of it. But it is the second sort which is usually sown in northern climates, Rath-ripe or Patney Barley.—Siberian Barley, called *Himmelgerste* or *Himmelskorn* by the Germans; *Himmelsbyg* or *Thorebyg*, by the Danes; *Himmelskiorn*, by the Swedes; and *Orge Celeste*, by the French, was only introduced into England in May 1767. It has a broader blade, of a much deeper green, than common barley at first coming up. The ears are shorter, having only from five to nine grains in length, whereas those of the common sort have from nine to thirteen; and in all stages it is a fortnight forwarder than common barley. The two sorts being sown in the same field on the 28th of April 1774, to the quantity of three bushels of each, the common barley produced thirty-six bushels and a half, weighing fifty-two pounds each, and the Siberian produced thirty-two bushels, weighing fifty-eight pounds each. But the soil was very dry, and much inclined to a gravel, greatly to the disadvantage of the Siberian barley, which requires a richer land. We shall now direct our attention to the propagation and culture of this most important article of produce. The directions here given will apply generally to the four first species of this genus, all the sorts of which are sown in the spring of the year, in a dry time, in some very dry light land. The usual time is early in March, but in strong clayey soils, it is not sown till April, and sometimes not until the beginning of May; but when it is sown late, if the season does not prove very favourable, it will be late in autumn before the barley become fit to mow; unless it be the rath-ripe sort, which is often matured in nine weeks after the seed has been sown. Some sow barley upon land where wheat grew in the former year; but when this is practised, the ground should be ploughed in the beginning of October during dry weather, and laid in small ridges, that the frost may have more power over it; which will render it mellow, and greatly improve it. This should be ploughed again in January, or at the beginning of February: it will break and prepare the ground better; which should be ploughed a third time in March, and laid even where it is not very wet; but in strong wet lands, the ground should be laid round, and the furrows made deep to receive the wet. When this is finished, the common method is to sow the barley-seed with a broadcast at two sowings; the first being harrowed in once, the second is harrowed in until the seed is buried; the common allowance of seed is four bushels to an acre. This is the quantity of grain usually sown by the farmers; but if they could be prevailed on to alter this practice, they would soon find their account in it; for if less than half that quantity be sown, there will be a much greater produce, and the corn will be less liable to lodge; for when corn or any other vegetable stands very close, the stalks are drawn weak, and incapable of resisting the force of winds, or bear up under heavy rains; but when they are at a proper distance, their stalk will be more than twice the size of the other, and are seldom laid. In fields where there has been a foot-path through the middle, the corn which came up thin on each side the path has been observed to stand upright, when all the rest on either side has been laid flat upon the ground: and whoever will observe these roots of corn near the paths, will find them tiller out, that is, have a greater number of stalks by four times than any other parts of the field. Experiments have been made by sowing barley in rows, so that the roots were three or four inches asunder in the rows; and the rows a foot distance; the

intermediate spaces of the same field were at the same time sown broadcast in the usual way; and the consequence was this, the roots which stood thin in the rows tillered out from ten or twelve to upwards of thirty stalks on each root; the stalks were stronger, the ears longer, and the grain larger, than any of those sown in the common way; and when those parts of the field where the corn was sown in the usual way have been lodged, the parts thinly sown have maintained their upright position against wind and rain, though the rows have been made not only lengthways but cross the lands in several positions, so that there could be no alteration in regard to the goodness of the land, or the situation of the corn: therefore where these experiments have been frequently made, and always attended with equal success, there can be no room to doubt which of the two methods is more eligible, since, if the crops were only supposed to be equal in both, the saving more than half the corn sown is a very great advantage, and deserves national consideration, for in scarce times such a saving might be of great importance to the public. It is true, farmers in general are very apt to complain if their corn does not come up so thick as to cover the ground green in a short time like grass-fields: but it is often observed, that when from the unfavourableness of the season it has come up thin, or when part has been accidentally killed, the corn has been much stronger, the ears longer, and the grain plumper, so that the produce of those years has exceeded that of other years when it had come up thick. The natural growth of corn is to send out many stalks from a root, and not to rise so much in height; therefore it is entirely owing to the roots standing too near each other that the stalks are generally drawn up tall and weak. I have had, (says Mr. Miller,) eighty-six stalks upon one root of barley, all of which were strong, producing longer ears and better-filled grain than any which I ever saw in the common method of husbandry, although the land upon which it grew was not remarkably rich: but I have frequently observed on the side of hot-beds in kitchen gardens, where barley-straw has been used for covering the beds, that some of the grains left in the ears having dropped out and grown, the roots have produced from thirty to sixty stalks each, every one three or four times larger than they ever grow in the common way: but to this, continues Mr. Miller, I know it will be objected, that although upon rich land in a garden these roots may probably have so many stalks, yet in poor land they will not produce so much, and therefore a greater quantity of seed must be sown to make the crop worth standing. Now this is one of the greatest fallacies that can be imagined, to suppose that poor land can nourish more than twice the number of roots in the same space as rich land; yet it is the general practice to act upon this absurd supposition as if it were really true. A greater quantity of seed is allowed for poor land than for richer ground, the sower not considering that where the roots stand so close they will deprive each other of their nourishment, and starve themselves; which is always the case where the roots stand close. The truth of this will be evident to any person who will observe that part of a field where the corn happens to be scattered in sowing it, and those places where by harrowing the seed is drawn up into heaps; the latter will starve, and never grow to a third part of the size to which they attain wherever the seed happens to have been loosely sown: yet common as this is, our farmers surely cannot be aware of it, otherwise they would not continue their old mode of sowing: if they know it, their prejudice must be strong in the extreme. When the barley is sown, the ground should be rolled after the first shower of rain, to break the clods and lay the earth smooth, which will render it better to

mow, and also cause the earth to lie closer to the roots of the corn; which will be of great service to it in dry weather. Where barley is sown upon newly broken-up land, the usual method is to plough up the land in March, and let it lie fallow until June, at which time it is ploughed again, and sown with turnips, which are eaten by sheep in winter. The dung of the sheep greatly improves the land; and in March following the land is ploughed up again, and sown with barley as before. Many persons sow Clover with their barley; some have sown Lucerne with it; but this is not judicious, for where there is a good crop of barley, the clover or lucerne must be so weak as not to pay for standing; so that the better way is to sow the barley alone without any crop among it, and then the land will be at liberty for any other crop when the barley is taken off the ground: yet this custom of sowing clover, rye-grass, and other grasses, with corn, has been so long and universally established among farmers, that we have little hope of prevailing upon them to relinquish this absurd practice, which can only be defended upon the ground of its having been handed down to them by their predecessors. When the barley has been up three weeks or a month, it will be a very good method to roll it over with a weighty roller, which will press the earth close to the roots of the corn, and thereby prevent the sun and air from penetrating the ground, which will be of singular service in dry seasons. This rolling of it before it stalks, will cause it to till out and produce a greater number of stalks; so that if the plants should be thin it will cause them to spread so as to fill the ground, and likewise strengthen the stalks. The time for cutting barley is when the red colour of the ears is off, the straw turns yellow, and the ear begins to hang down. In the north of England the barley is always reaped and made up into sheaves like wheat, by which method less corn is lost, and the whole may be more conveniently stacked. But this cannot be so well practised in rich lands like those in the neighbourhood of London, where there are weeds among the corn; and especially in moist seasons: in these cases the barley must lie on the swathe till all the weeds are dead; and as it is apt to sprout in wet weather, it must be shaken up and turned every fair day after rain, to prevent it. When carried in, it ought to be thoroughly dry; for if stacked wet it turns musty, and if too green will burn in the mow. The common produce of barley is two and a half or three quarters on an acre.—*Soil proper for barley.* The best soil for barley is the dry and healthy, rather light than stiff, yet of sufficient tenacity and strength to retain the moisture. If the land be poor, it ought also to be dry and warm; and if so, will often produce better corn than richer land in a cold and wet situation. Much barley, however, is grown on heavy land, both after wheat and on a fallow; but this is no proof of its being a good rule, for we have already shewn the unreasonable nature of several of the customary modes of cultivating this grain.—*Succession and preparation of land.* Barley usually succeeds wheat or turnips, sometimes vetches and other crops, or is put in on a fallow or on turf. After wheat, the soil is winter-fallowed by three ploughings: the first lengthways in November; the second across in March; and the last or seed-ploughing lengthways like the first. The soil is harrowed between the two last ploughings, and the quick, if any, destroyed. In Norfolk, when wheat-sowing is finished, the farmer begins to *scale* in his wheat-stubbles for a winter fallow. If the land lies in narrow work, the ridgelets are split; if in warps, the ground is likewise ploughed clean, but very fleet. At the beginning of March the land is harrowed, and presently after the wheat-stubbles are taken up by a full pitch cross-ploughing; or, if the season be wet, and the soil heavy, he reverses the ridges. In April he harrows, and

begins stirring for barley, with another full pitch-ploughing lengthways; generally gathering the soil either into five-pace, or ten-pace warps, in which it lies until seed time; when it is harrowed, rolled, sown, ploughed fleet, reversing the warps, and *slading* down the furrows; so as to render the entire surface as even and level as may be. After turnips the soil is generally broken up as fast as the turnips are got off; if early in winter, by rice-balking; if late, by a plain ploughing. The general practice, if time will permit, is to plough three times; the first fleet or shallow, the second full-pitch, and the last a mean depth, with which the seed is ploughed in. But when it is late before the turnips are got off, sometimes the ground is only ploughed once, and the seed sown above; but more frequently it is broken by three ploughings, as above, even when there is not more than a week to perform them in. Such is the practice in Norfolk, where the farmers are generally very skilful in the art of cultivating barley. They seem fully aware of the tenderness of this plant in its infant state, and of its rootlings being unable to make the necessary progress in a compact or cold soil, and therefore exert every means in their power to make their soil friable and pulverous. To this intent it is sometimes two-furrowed, and even a fourth earth is given, especially in a cold wet season. Nor is this caution confined to Turnip-barley, but should be extended more or less to Stubble-barley, which certainly requires less care. As the soil is kept open by the indigested stubble, and the roots of grasses and other weeds, from which turnip-fallows at least ought to be free, that will perhaps account for the superiority of Stubble-barley, over that produced by a turnip-fallow, however well-timed and manured. In Essex they plough five times; four in the fallow year, throwing the land on to the ridge for winter by the fourth; then they take the first opportunity of hard frosts to carry on their composts, at the rate of twenty or thirty loads to the acre. The compost consists of farm-yard dung mixed up with turf. They then take care, as soon as the land is dry enough, to plough and sow the barley from the last week of February to the middle of April; but if the seed is not in the ground in March, they despair of a great crop. This barley culture is very good. It is an excellent practice to plough and sow in the spring, instead of giving preparatory ploughings when the seed should be in the earth. When barley is put on turf, or after hay, as clover, &c. the turf is generally broken by a winter fallow, and the soil treated in other respects as after wheat. In very light dry soils it may be right to break the flag as little as possible, provided the grass be killed; in this case they do not break up the turf till after Christmas. With this process the Norfolk farmers sow the barley above furrow. Barley is seldom manured for, except when sown after lay: after wheat and turnips no manure can be requisite, if the ground had been manured for the former, but on a fallow it is manured as for wheat.—*Quantity of seed, preparation for, and method of sowing.* In addition to what has been already advanced on this head in the former part of the present article, we have to observe, that many farmers sow four bushels of seed on an acre, while some few sow no more than two bushels. Four bushels is very general, but in some places three bushels and a half, and in others three bushels, is the average or medium quantity of barley sown. The following experiments confirm Mr. Miller's theory of sowing thinner on poorer soils. On an acre of poor land, worth three and six-pence per acre, two bushels of barley were sown: on the next adjoining acre, three bushels; and on the next, four bushels. The result was, that the crop was best from two bushels, next best from three, and the worst from four, which is the greatest quantity of seed that ought ever to be sown.

Brining and liming seed-barley previously to sowing it, is a common practice, which is reprobated by some, who think even liming prejudicial. Such as are of the latter opinion, recommend the sprinkling a little soot in the water, to secure the seed from insects. It is certain that barley which has been wetted for malting, and begins to sprout, will come up sooner in a dry seed-time; and in such a season this grain will not only lie long in the ground, but come up and ripen very unequally. To avoid these evils, and give the infant barley an advantage over seed-weeds, and a chance of coming to market sooner, it seems a good method to steep the seed intended for sowing. This may be either done in clean water, or the drainings of the dung-heap, in which it may lie covered for twenty-four hours, or even longer, if the land be dry, and there be no likelihood of rain for ten days. Sow the grain wet from steeping, without any thing, or with sifted wood-ashes. The sower must put in a fourth or a third more seed in bulk than he would of dry grain, the seed being swelled in that proportion; and he may expect it up in a fortnight at farthest. The common method of sowing barley is broadcast at two sowings; the first harrowed in once, the second twice. In Norfolk, almost all the barley is sown under-furrow; that is, the surface having been smoothed by the harrow and roller, the seed is sown and ploughed under with a shallow furrow: a method admirably adapted to a light dry soil; and indeed to any soil which is light enough to produce good barley, provided it be rendered sufficiently fine, and the seed be not buried too deep. However, if the season be wet and the soil cold and heavy, good farmers not unfrequently sow barley above, as is the general custom in other countries. And this seems to be a reasonable practice; for in a dry spring and light land, sowing under seems most eligible; and in a cold spring, or when the soil is rough with clods, sowing above appears to be equally good management.

—*Drill-sowing.* Grain sown by hand broadcast must fall at unequal depths; the seeds consequently sprout at different times: that which is buried where the earth is moist soon appears, whilst such as is near the surface lies baking in the heat of the sun, and does not vegetate till plentiful rains have moistened the soil: hence that inequality of crop to which barley is particularly liable. Of the two common methods of sowing barley, ploughing-in buries too deep, and that sown under the harrow is too much exposed to birds; whereas by the drill the seed is all regularly deposited at the proper depth. To this advantage peculiar to drilling, we may add the saving which is made in the seed, and the opportunity this plan affords of keeping the crop perfectly clean by hoeing. The quantity of seed used in drilling by different persons is from six pecks to three bushels; but it is bad economy in general to be too niggardly of seed, and therefore it is not advisable to sow less than two bushels on an acre. If, however, it should be thought proper to use even three bushels, that will secure a considerable saving. Drilling indeed cannot be so well practised on heavy soils; but it may have place on those which are light and friable, which are peculiarly adapted to barley. Such soils as are not injured by horses going repeatedly on them, and being almost always under command, the horse-hoe may go over them whenever the farmer is most at leisure. Dr. Hunter, in his *Georgical Essays*, gives the following account of an experiment upon this subject. "In the spring of the year 1769, I sowed an acre of barley in equidistant rows, with the drill-plough, in a field which was sown with the same grain, and upon the same day, broadcast. The broadcast took three bushels per acre; the drill required only six pecks. The drills were eight inches asunder, and the seed was lodged about two inches within

the soil. The acre was drilled within the hour. In the course of growing, the drilled barley seemed greener, and bore a broader leaf than the broadcast. When the ears were formed throughout the field, the ear of the drill-barley was plainly distinguished to be nearly half an inch longer than the broadcast, and the grains seemed fuller and better fed. Being at a loss to account for this, (continues Dr. Hunter,) I dug up some roots of both, and found that the pipe of communication between the seminal and coronal roots of the drilled barley was considerably longer than in the broadcast. The produce of two hundred square yards of the broadcast and drilled barley was carefully housed, and afterward threshed out. The drilled exceeded the other nearly one-fifth in measure, and was two pounds heavier per bushel."—*Time of sowing barley.* The farmer is governed by seasons, and by other necessary work which he may have to perform; but to sow early when he can, is one of the most important precepts in the culture of barley. If three ploughings can be given in time, it is best to get in the seed some time in March at farthest; and some farmers, rather than defer the sowing, will throw in the crop on one earth. In Norfolk, they commonly sow on their light lands in April, and on the moist lands in May; and they think that, where they are much subject to weeds, they have the best crops when they sow late. Early sowing, however, has been gaining ground for some years past. And it appears from an experiment accurately made by a very intelligent cultivator, that more grain was produced from sowing in January, than at any other time. The land was a deep sand, valued at six or seven shillings the acre; it had been under clover, and was ploughed as for wheat in November, in the middle of which month two bushels of barley were sown and harrowed in upon one earth only. The same quantity was sown in the middle of every month till the following May inclusive. The first sown came up a week sooner than the wheats sown on the same day by the side of it, and was very flourishing till the first sharp frost set in, which damaged the blade, but did not seem to affect the root. The other sowings had two earths; one cast, or half the seed, was ploughed in, and the other half harrowed in; the second sharp frost killed some of the second sowing, and a good deal of the first; but both together, with the third sown in January, seemed to suffer still more by the sharp cutting winds in the month of March, when there was no snow to cover the blade. These three sowings, particularly the first, had their plants very much thinned by the frosts and winds; although the roots that were left stubbed very much in the spring, and had very long ears, with from thirty to thirty-six grains in each. The sowings in February and March lost few if any of their plants, and were both forward enough to be harvested on the same day with the preceding sowings. That sown in April was a full fortnight later, and the last, sown in May, was entirely destroyed by rooks, there being no other sown so late in the neighbourhood. It would have been the same with the early sowings, had not the evil been guarded against. However advantageous therefore early sowing may be, yet neither this nor any other laudable practice will be of any avail in open fields where lands are intermixed, unless where there is a general consent; and if one farmer only were to sow early, he must have as many keepers as he has pieces of land, and thus obtain better crops than his neighbours at a ruinous expence. The whole land sown in the above experiment was seventy-two square yards, or little more than two-thirds of an acre; and all the sowings were by the side of each other on the same piece of land. Three swaths of each sowing, twelve yards in length, where the soil was most equal, were threshed out, and each parcel was dressed and measured into

a sack separately as soon as threshed. All the barley sown was of the Zealand stock, and the produce was as follows:

			Comb.	Bush.	Peck.	Qrt.
1 November,	3 Pecks of Seed per Acre produced	12	2	1	0	
2 December,	3 Pecks 1 Pint.....	12	3	1	1½	
3 January,	3 Pecks 4 Pints.....	13	0	0	6	
4 February,	2 Pecks 14 Pints.....	11	2	2	2	
5 March,	2 Pecks 10 Pints.....	10	3	3	7	
6 April,	2 Pecks 2 Pints.....	8	3	2	5	

Cultivation after seeding. Whether grass-seeds be sown over the barley or not, the surface is harrowed presently after the last ploughing; and when the barley is up, it is run over with a light roller, to break the clods, and close the earth about the roots. Of this, however, we have treated before, and have only to add, that in heavy lands if the harrow leaves any clods, they are broken with the clodding beetle, and if any quick is pulled up, it is destroyed. When the barley has been up three weeks or a month, it is a good way to roll it again with a heavy roller, which will prevent the sun and air from penetrating the ground so as to injure the roots. It will also cause the barley to tiller out, so that if the plants be thin, the ground will be filled, and the stalks strengthened. If the blade should grow too rank, mowing is a much better method than feeding it down with sheep; because the scythe takes off only the rank tops, but the sheep, being fond of the sweet end of the stalk next the root, will often bite so close as to injure its future growth.—There are two preparations of barley to be met with in the shops, the one called French or Scotch, the other Pearl Barley. Two ounces of either of these, after being washed from the mealy matter which adheres to them, in cold water; then boiled a few minutes in about half a pint of water, which is to be thrown away; and, lastly, put into two quarts of boiling water, and the coction continued till one half is wasted; makes a most elegant and grateful beverage, which is extremely useful in the gravel, stone, strangury, and heat of urine; likewise in fevers of the ardent kind, and other acute disorders, where cooling and diluting fluids are necessary. A strong infusion of malt in boiling water is a pleasant, and frequently efficacious, remedy for worms in children.—For further particulars, see *Triticum*.

2. *Hordeum Hexastichon*; *Winter or Square Barley*, or *Bear*, or *Big*. All the florets hermaphrodite, and awned, the grains placed regularly in six rows. This has a much thicker spike than the common Spring Barley, and is also much shorter, but the number of grains in each ear or spike is greater in the proportion of at least three to two. I have frequently counted forty-two grains, when common barley had only twenty-two. The ear is seldom more than two inches in length; it is square, with two rows of grains on two of the sides; on the other two, a single row of grains runs up the middle, so that the former rows are awned only laterally, and the latter on the sides and along the middle also. The lower flowers are imperfect in both; the outer valve of the corollas has a rough awn or beard, from four to six inches in length.—This species is rarely cultivated in the southern parts of England, the grain, though large and plump, not being esteemed so good for malting, as common barley; but in the northern counties, and in Scotland, it is generally sown, because it will bear the cold much better. In some of the more southern parts of Europe it is sown in autumn.—For the best methods of cultivating it, see the preceding species.

3. *Hordeum Distichon*; *Common Barley*. Lateral florets male, and awnless; grains angular, imbricated. This essentially differs from the two preceding species; the spike or ear is very long, flattened, or transversely greater in breadth than

thickness, with a double row of defective, or male, and consequently barren florets, on each flat side, and a single row of fertile florets at each edge. The valves of the calix, outer glume, husk, or chaff, are linear, and shorter by half than the corolla or inner chaff, which ends in an awn or beard that is straight, and sixteen times its own length: when ripe it is coriaceous, angular, and continues close about the grain; when this is taken off, the grain appears of an ovate form, grooved, and angular. There is a variety which, according to Mortimer, was cultivated in Staffordshire; a sort of naked Barley, or Wheat-Barley, the ear shaped like barley, but the grain like wheat. It was much sown at Rowley, Hamstal, and Redmore, where they call it French Barley; and adds, that it yields well, and makes good bread and malt. As this grain is not noticed in Mr. Pitt's View of the Agriculture of this county, drawn up for the consideration of the Board of Agriculture, and printed in 1796, we may conclude that it is no longer cultivated in Staffordshire. Villars describes it as having a larger finer grain, of the size and weight of wheat, and separating from the husk; from which it derives its name. It is more difficult to cultivate, but yields a larger produce, and is of a better quality, than the common barley.—See the first species.

4. *Hordeum Zeocriton*; *Sprat or Battledore Barley*. Lateral florets male, awnless; grains angular, spreading, corticated. This differs from the common sort, in being of a lower stature, and in having a shorter and broader ear, with closer grains, standing out more from the rachis, and having shorter awns. Between the two rows of fertile flowers, are two other rows of male or barren flowers, as in the preceding species, but more conspicuous.—Under this last of the edible species of this genus, we shall subjoin the various names of the grain, which these first four species alike produce, and which the press of more important matter excluded from the particulars detailed in the first. It may be useful to know what names different nations call this important article of sustenance. The German name is *Gerste*; the Dutch, *Gerst*; the Danish, *Byg*; the Swedish, *Biugg*, *Kiorn*, or *Korn*; the French, *Orge*; the Italian, *Orzo*; the Spanish, *Cebada*; the Portuguese, *Cevada*, or *Sevada*; and the Russian, *Jetchschmen*, or *Jesmin*.—For the cultivation of this species, see the first species.

* Grasses.

5. *Hordeum Bulbosum*; *Bulbous Barley-grass*, or *Rye-grass*. All the florets in threes, fertile, awned; involucre bristle-shaped, ciliate. This has obtained its name from its bulbous roots, wrapped up in whitish or brownish broad membranaceous fibrous coats, and having strong fibres hanging from them; culms two or three, from a foot or eighteen inches to three and even four feet high, in different situations; leaves a span or a foot, sometimes only a hand long, a line and half or two lines wide; spike narrow, three or four, sometimes nearly six inches long, and three or four lines broad.—Native of Italy, and the Levant. See *Grass*.

6. *Hordeum Murinum*; *Wall Barley-grass*. Lateral florets male, awned; middle involucre ciliate. Common Wall Barley-grass, Way-barley, Way-bennet, or rather Way-bent; called also Wild Rye, or Rye-grass; has an annual root; numerous stems a foot or eighteen inches in height, round, smooth, frequently branching at bottom, where they are procumbent, and bend at the joints; leaves from three or four to six inches in length, and a quarter of an inch in breadth, covered with a soft down on both sides; spikes from two to three inches long, pale green. This is a very common grass by the side of paths and under walls, whence its trivial names both in Latin and English. It flowers during the

greater part of the summer, and is said to be well known to the innkeepers of the isle of Thanet, under the name of Squirrel-tail grass. They find that if horses feed on it some time, the beards stick into their gums, and make them so sore that they are in danger of being starved. This fact seems corroborated by the circulation of handbills, informing travellers that at such inns they might depend on having hay without any mixture of squirrel-tail grass; but as Wall Barley-grass is never found in the body of a meadow, it may be doubted whether it is not the next species which produced this bad effect; and if so, that cannot be recommended as fit for culture. It is an old notion, that this grass is Barley degenerated, though it bears most resemblance to Rye: the error is too vulgar and obvious to require refutation. The Germans call this species *Mansegerste*, *Gerstengras*, &c. the Dutch, *Muurgerst*, *Bastardgerst*, *Muizenkorn*; the Danes, *Byggræs*, *Fandens-ær*; the Swedes, *Villkorn*; the French, *Orge des Murs*. See *Grass*.

7. *Hordeum Pratense*; *Meadow Barley-grass*. All the florets awned, the lateral ones male; all the involucels rugged. Linneus supposed this to be a mere variety of the preceding: Ray however observes, that it differs in being much taller, and having shorter spikes and awns. Its height is almost double that of the other; the spike is greener, only half as long, and square, with the awns of the calix as long as those of the corolla. The middle floret is smooth; the two laterals, though they have a pistil as well as stamina, yet being minute, never come to maturity. Mr. Miller pronounces this to be a very good grass for pastures, and says it has perennial roots with leafy stalks, which do not become stiff and harsh; and that if duly rolled, the roots will mat, and form a very close sward. It is however a late grass, and thought to be less productive than some others. See *Grass*.—For *Rye-grass*, which is sometimes, but erroneously, called *Rye-grass*, see *Lolium Perenne*.

8. *Hordeum Maritimum*; *Marsh Barley-grass*. All the rugged flowers awned, the lateral ones male; involucels rugged, the interior ones of the males semi-lanceolate. This grass at first sight resembles the common Wall Barley-grass, inasmuch that it might be doubted, until experiments are made by culture, whether it be a distinct species; because salt water and sea air will alter the appearance of grasses. It differs however in having shorter pyramidal spikes, made up of a greater number of florets more crowded together, with the awns more standing out, those at bottom longest, and becoming gradually shorter towards the top of the spike.—This is marked as annual both by English and foreign botanists. Allioni says it evidently differs from the next species, and that in cultivation it acquires a loftier culm, with a spike twice or thrice as long as in the wild plant, but that the character of the incurved culm continues. It flowers in June and July. Native of Barbary, and the southern parts of Europe and of England, in salt marshes near the sea.

9. *Hordeum Jubatum*; *Long-bearded Barley-grass*. Awns and involucels bristle-shaped, and very long; the stem-leaves are four or five inches long, and a line or a line and a half wide, villose with short hairs above; below, especially towards the top, rough if drawn downwards through the fingers. This has the habit of the sixth species, but the involucels and bristle-shaped awns are four times the length of the whole spike, which gives this grass a singular appearance. Linneus calls it a native of Canada, but subsequently a native of Smyrna; in which Scheuchzer coincides. The *New Catalogue* assigns it to Canada and Hudson's Bay, and calls it a biennial plant. There is much uncertainty concerning it.—For the two last species, see *Grass*.

Hot-beds, are beds used in gardening, made with fresh horse-dung or tanner's-bark, and covered with glasses, to defend them from cold winds. They appear to have been long known and used in our gardens. By the skilful management of them, we may imitate the temperature of warmer climates; by which means the seeds of plants brought from any of the countries within the torrid zone, may be made to flourish under the intense cold of the most inhospitable regions. Hot-beds should be formed in a dry piece of ground, under a sunny exposure, well fenced in either by walls or good ship planks, ten feet high to the north, and six feet high to the south, apart from the rest of the kitchen garden, and as near to the stable dung-heap as possible, to avoid labour and dirt in barrowing. Sixty feet in breadth, and an hundred feet in length, will contain a sufficient extent of ground for winter framing for Mushroom-beds; forced Asparagus, Peas, Kidney-beans, Strawberries, Radishes, Salad-herbs, early Cucumbers and Melons; annuals for the flower-garden; to bring forward perennials and shrubs, as Pinks, Carnations, bulbous plants, Lily of the Valley, Roses, Honeysuckles, and innumerable others. Under the south fence there may be frames for forcing fruit, the management of which is directed under the respective articles. If the dung employed in making hot-beds be new and strong, there will be no necessity for mixing sea-coal ashes, leaves of trees, or tan, as Mr. Miller directs; these are of use only for strengthening the heat, and rendering it more durable, when the dung is in some measure exhausted by having been too long in the dung-heap. In fresh dung, these additions frequently render it too fierce and burning. The hot-beds commonly used in kitchen gardens are made with new horse-dung mixed with the litter of a stable, and a few sea-coal ashes, when the dung is not fresh. This should remain six or seven days in a heap, and being then turned over, and the parts mixed well together, it should be again cast into a heap; where it may continue five or six days longer, by which time it will have acquired a due heat. The hot-beds are then made in the following manner. Dig out a trench of a length and width proportionable to the frames you intend it for; and if the ground be dry, let it be about a foot or a foot and a half deep; but if wet, not more than six inches; then wheel the dung into the opening, observing to stir every part of it with a fork, and lay it even and smooth all over the bed, placing the bottom part of the heap, which is commonly free from litter, upon the surface of the bed; and if it be intended for a bed to plant out cucumbers for good, you must make a hole in the middle of the place designed for each light, about ten inches over and six deep; which should be filled with good fresh earth, thrusting in a

stick to show the places where the holes are; and then cover the bed all over with the earth that was taken out of the trench, to the depth of four inches; and put on the frame, letting it remain till the earth be warm, which commonly happens in three or four days after the bed is made, and then the plants may be placed in it. But if the hot-bed be designed for other plants, there need be no holes made in the dung; but, after having smoothed the surface with a spade, you should cover the dung about three or four inches thick with good earth, putting on the frames and glasses as before. In making these beds, care must be taken to settle the dung close with a fork; and if it be pretty full of long litter, it should be trod down equally on every part. During the first week or ten days after the bed is made, you should cover the glasses but slightly in the night, and carefully raise them to let out the steam; but as the heat abates, the covering should be increased; and as the bed grows cold, fresh dung should be added round the sides of it. The hot-bed made with tanner's bark, is however much preferable to that described above, especially for all tender exotic plants and fruits, that require an even degree of warmth to be continued for several months; which cannot be produced by horse-dung. The manner of making them is, first dig a trench about three feet deep in dry ground, and not above a foot in wet soils. This trench must be raised two feet above the ground. The length must be proportioned to the frames intended to cover it, but it should never be less than ten or twelve feet long, and six wide. The trench should be bricked or planked up round the sides, to the abovementioned height of three feet, and filled in the spring with fresh bark, recently drawn out of the tanner's vats, and from which also all the moisture has been previously drained, by laying it in a heap for three or four days. As the bark is put in, beat it down gently, and equally, with a dung fork; but it must not be trodden, for that would prevent its heating, by settling it too close. When this is done, put on the frame, covering it with glasses; and in about ten days or a fortnight it will begin to heat; at which time plunge your pots of plants or seeds into it, observing not to tread down the bark in doing it. These beds will continue three or four months in a good temper of heat; and if you stir up the bark pretty deep, and mix a load or two of fresh bark with the old when you find the warmth decline, you will preserve its heat two or three months longer. Many persons lay hot horse-dung in the bottom of the trench, under the bark; but this ought never to be practised, unless the bed be wanted sooner than the bark would heat of itself, and even then there ought only to be a small quantity of dung at the bottom. The frames which cover these beds, should be proportioned to the different plants they are designed to contain. If they are to cover the Ananas or Pine-apple, the back part of the frame should be three feet and a half high, and the lower part fifteen inches, which will be a sufficient declivity to carry off the wet; and the back part will be high enough to contain the large fruiting plants, and the lower side will be sufficient for the shortest plants; so that by regularly placing them according to their height, they will not only have an equal distance from the glasses, but also appear much handsomer to the sight. And although many people make their frames deeper, that is certainly high enough to contain the plants without bruising their leaves, and is much better than allowing them a larger space; for the deeper the frame is made, the less will be the heat of the air inclosed therein, there being no artificial warmth but what the bark affords, which will not heat a large space of air: therefore as the pine-apple requires to be

constantly kept very warm, in order to ripen the fruit well, it must follow, a greater depth will not be so favourable. But if the bed be intended for taller plants, then the frame must be made in depth proportionable thereto; but if it be for sowing seeds, the frame need only be about fourteen or sixteen inches high at the back and seven inches deep in the front, by which means the heat will be much greater, and it is commonly the proportion of the frames usually employed in kitchen gardens. Their length is generally according to the fancy of the owner; but they commonly contain three lights in each, and are generally about eleven feet long. They sometimes contain four lights; but this is too great a length for the boxes, for the frames thus made are not so handy to remove as when they are shorter, and are more subject to decay at the corners. Some indeed have them to contain but two lights, which is very handy for raising Cucumbers and Melon plants while young; but is too short for a bark-bed, as it will not admit a sufficient quantity of bark to continue the warmth for any considerable time. Whenever frames are made very deep, it is much the better way to have them made to take asunder at the four corners, so that they may be removed with ease, and that the frame may not be spoiled by the difficulty in pulling it off to put in new bark, or remove the old. Farther directions respecting hot-beds and their management may be found in the culture prescribed for Cucumbers and Melons under the article *Cucumis*.

Hot-House. See *Stove*.

Hottentot Cherry. See *Cassine Maurocenia*.

Hottonia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-parted; parts linear, from erect spreading. *Corolla*: one-petalled, salver-shaped; tube the length of the calix; border five-cleft, flat; clefts ovate-oblong, emarginate. *Stamina*: filamenta five, awl-shaped, short, upright, opposite to the clefts of the corolla, and placed on the tube; antheræ oblong. *Pistil*: germen globular, acuminate; style filiform, short; stigma globular. *Pericarp*: capsule globular, acuminate, one-celled, placed on the calix; seeds very many, globular; receptacle globular, large. ESSENTIAL CHARACTER. *Corolla*: salver-shaped, *Stamina*: placed on the tube of the corolla. *Capsule*: one-celled.—The species are,

1. *Hottonia Palustris*; *Common Water Violet*. Peduncles in naked whorls of several flowers; leaves in whorls, pinnate. The root consists of numerous white capillary fibres, which strike deep into the mud. The stem is a scape a foot high, simple, upright; flowers pale purple or white, with a yellow eye, in several whorls one above another, forming altogether a handsome spike. This singular plant has the leaves under water, and the upper part of the flowering stem only above. The flowers are beautiful, and the leaves afford a refuge, perhaps even nourishment, to the fresh-water Periwinkle and other small shell-fish. It abounds in ditches and marshes, stagnant waters, and slow-running streams, flowering in May and June, and continuing a long time in flower. There is a variety with smaller leaves.—The old writers call this plant *Millefolium*, from the abundance of its leaves; and *Viola*, which was a favourite name for the Stock Gilliflower, and many other handsome-flowered plants besides the violet. The English, besides Water Violet, call it Water Milfoil or Yarrow, and Water Gilliflower; the Germans name it, *Wasserviole*; the Dutch, *Waterviolier*; the Danes, *Vandrollike*; the Swedes, *Vattenrolleka*; the French, *Plumeau*, *Plume d'Eau*, *Plumette*, *Violette Aquatique*, *Giroflée d'Eau*, *Millefeuille d'Eau*, *Hottone*; and the Italians, *Miriofollo Aquatico*. This elegant species may be propagated in deep standing waters

by dropping the seeds as soon as they are ripe into the water, where they are designed to grow; and if not disturbed they will appear and increase abundantly in the following spring.

2. *Hottonia Indica*; *Indian Water Violet*. Peduncles axillary, one-flowered; leaves in whorls, trifid or thrice trifid; stem a finger's length, quite simple. Linneus says the genus of this plant is doubtful.—Native of Ceylon.

3. *Hottonia Sessiliflora*; *Sessile-flowered Water Violet*. Flowers in leafy whorls, sessile; leaves in whorls, bipinnate and trifid; stem simple, sometimes with a branchlet at top.—Found by Burmann in the East Indies.

4. *Hottonia Littoralis*; *Sea-water Violet*. Leaves ovate-oblong, opposite, quite entire; flowers solitary; stem commonly quite simple, about eight inches high, upright. The flowers are purple, axillary, and peduncled, resembling those of the second species, but the leaves are very different.—Native of Cochin-china.

Hovenia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, hairy at the base within, permanent, five-parted; parts ovate, reflex, deciduous. *Corolla*: petals five, obovate; very obtuse, patulous, rolled up, involving the stamina, inserted into the calix between the segments, and of the same length with them. *Stamina*: filamenta five, inserted into the base of the calix, and a little shorter; antheræ roundish, hid within the petals. *Pistil*: germen superior; style upright, much shorter than the calix; stigmas three, from patulous reflex, blunt. *Pericarp*: capsule ovate, globular, three-furrowed, three-celled, three-valved. *Seeds*: solitary, lens-shaped, very smooth. *Observe*. Sometimes, but seldom, the calix is four-parted, and there are only four stamina. **ESSENTIAL CHARACTER.** *Petals*: five, convoluted; stigma trifid. *Capsule*: three-celled, three-valved.—The only known species is,

1. *Hovenia Dulcis*. Root perennial; stem arboreous, thick, a fathom and half in height; branches round, smooth; leaves alternate, petioled, subcordate, ovate, acuminate, serrate, hanging down, nerved, smooth, a hand in length; flowers axillary and terminating, panicked; panicle dichotomous, compressed; peduncles subcylindric, dichotomous, thickening after flowering-time with a sweet red pulp, which is eaten by the Japanese, and tastes somewhat like a pear. The flowers, which readily fall off, appear from June to August, and ripen into fruit in November.—Native of Japan, near Nagasaki.

Hound's Tongue. See *Cynoglossum*.

House-leek. See *Sempervivum*.

Houstonia; a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, four-toothed, upright, permanent. *Corolla*: one-petalled, funnel-shaped; tube cylindric, long; border four-parted, spreading; parts roundish. *Stamina*: filamenta four, in the neck of the corolla, very small; antheræ simple. *Pistil*: germen superior, roundish, compressed; style simple, shorter than the stamina; stigma bifid, acute. *Pericarp*: capsule roundish, twin, gaping transversely at top, two-celled, two-valved; valves opposite to the partition. *Seeds*: few, (three or four,) small, ovate, adhering to the partition. Jussieu observes, that the germen of the second species is certainly inferior. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled, funnel-form. *Capsule*: superior, two-celled, two-seeded; according to Gærtner, three or four seeds in each cell.—The species are,

1. *Houstonia Cœrulea*; *Blue-flowered Houstonia*. Root-leaves ovate; stem compound; first peduncles two-flowered. This is a vernal plant, with terminating flowers. From a slender root it produces small, oblong, pointed leaves, spreading on the ground in a ring; among these, slender smooth stalks arise,

at the height of two inches, forming a joint, and furnished with two or three small leaves; here they divide into two and sometimes three slender branches or peduncles, an inch or two in length, and at the end of each a single blue flower. There is a variety with extremely slender stems, the peduncles of which are axillary, very slender, and oblong, having each a blue flower at the top, rather large for the size of the plant.—This variety is a native of Maryland, the other of Virginia.

2. *Houstonia Purpurea*; *Purple-flowered Houstonia*. Leaves ovate, lanceolate; corymbs terminating; flowers superior. This has leaves in pairs resembling those of Chickweed or large Alsine. The flower is of a reddish purple.—It is a native of Maryland, where it is also found with a narrower leaf.

3. *Houstonia Serpyllifolia*. Stalk procumbent; leaves spatulate, obtuse; peduncles terminating, long, bearing each a single blue flower.—Found upon high mountains near rivulets and springs from Virginia to Carolina.

4. *Houstonia Tenella*. Stalk creeping, filiform; leaves orbiculate, acute, nervose; peduncles terminal, very long, bearing each a single purple flower. It much resembles the preceding species, though something smaller.—Found on high mountains in North Carolina.

5. *Houstonia Angustifolia*. Stalk erect, very branchy, glabrous; leaves linear; flowers terminal, fasciculated, subsessile, purple-coloured.—Found in sandy fields along the sea-coast from Carolina to Florida.

Houttuynia; a genus of the class Monœcia, order Monandria; according to Thunberg, class Polyandria, order Polygynia.—GENERIC CHARACTER. *Male Flowers*. *Calix*: spathe four-leaved; leaflets ovate, concave, obtuse, coloured; spadix oblong, the length of the spathe, covered with fructifications. *Corolla*: none. *Stamina*: filamenta very many, intermixed with the germina, about seven round each germen, very short; antheræ twin, ovate. *Females*. *Calix*: spathe and spadix common with the males. *Corolla*: none. *Pistil*: germina very many, intermixed with the stamina; according to Loureiro, germina three-cornered; style none; stigmas three, oblong, reflex. *Pericarp*: capsule three-cornered, Loureiro says, three-celled, three-valved, opening at the top. *Seeds*: according to Loureiro, many, ovate, small. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: none; stamina mixed with the pistils, some say seven about each germen.—The only known species is,

1. *Houttuynia Cordata*. This plant has the habit of Polygonum, with stipules like that; root annual, fibrous; stems simple, herbaceous, grooved, flexuose, upright, a hand, a span, or a foot in height, smooth in all its parts; leaves alternate, petioled, cordate, cuspidate, entire, paler underneath; petioles striated, stipuled at the base, shorter than the leaf; flowers from the sheath of the petiole solitary, peduncled; peduncle the length of the petiole. It is difficult to determine the number of stamina in this genus, because there is no calix, corolla, or scales, to separate the germina. It ought however to be referred to the class Polyandria, the stamina being scattered over an elongated receptacle, among several germina.—Discovered by Thunberg in Japan, where it is very common in the ditches between Miaco and Jedo, flowering in May and June. Loureiro also found it in the gardens of Cochin-china, where it is eaten in salads, and is esteemed attenuant, resolvent, and emmenagogue.

Hudsonia; a genus of the class Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved, tubular, cylindric, with a patulous mouth; leaflets lanceolate-linear, blunt. *Corolla*: none. *Stamina*: filamenta fifteen, capillary, shorter than the calix; antheræ roundish. *Pistil*: germen superior, ovate; style filiform,

the length of the calix; stigma blunt. *Pericarp*: capsule cylindric, shorter by half than the calix, one-celled, three-valved. *Seeds*: three, rounded on one side, angular on the other. **ESSENTIAL CHARACTER.** *Calix*: five-leaved tubular; according to Jussieu, three-leaved, above three-parted. *Corolla*: none; petals five, and very small according to Bergius. *Stamina*: fifteen. *Capsule*: one-celled, three-valved, three-seeded.—The only species known is,

1. *Hudsonia Ericoides*, which is a shrub with the appearance and habit of heath. Branchlets filiform, scattered, imbricate; leaves subulate or cerosc, hirsute, when tender still more hirsute and hoary, so that those on the extreme branchlets seem as if they had leafy gems scattered over them; peduncles from the leafy gems solitary, filiform, longer than the leaves; calix erect, pubescent.—Native of New Jersey and Virginia.

Hugonia; a genus of the class Monadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved; segments ovate, acute, concave, coriaceous, permanent, the two outer ones larger; Gærtner says, five-leaved. *Corolla*: petals five, roundish, large, emarginate, spreading, narrowed at the base, fixed at the base by slender claws to the little pitcher or stamina. *Stamina*: filamenta ten, awl-shaped, equal, shorter than the corolla, connected at bottom into a little pitcher; antheræ roundish, furrowed, incumbent. *Pistil*: germen roundish; styles five, filiform, longer than the stamina; stigmas capitate, orbicular, flat. *Pericarp*: drupe globular, one-celled; according to Gærtner, a berried drupe. *Seed*: nut globular, deeply striated, ten-celled. *Kernels*: oblong, compressed, bowed at the back. *Observe.* The two outer segments of the perianth are wholly tomentose on the outside; the middle one is also tomentose, except that part where it is covered by one of the outer ones, and there it is smooth and shining, as are the two inner ones, which are tomentose only at the tip. The filamenta were alternately shorter in the flower which I examined. The alternate kernels seem frequently to be abortive, which is perhaps the cause why Cavanilles makes the fruit to be five-celled. In the drupe which Schreber opened, there were more than five kernels. **ESSENTIAL CHARACTER.** Five-styled. *Corolla*: five-petalled. *Drupe*: with a striated nut.—One species only is known.

1. *Hugonia Mystax*. Spines opposite, revolute. This is a tree, with an irregular bark. Branchlets short, alternate, spreading, leafy at the end; leaves oval, quite entire, smooth, petioled, clustered; flowers several, in clusters from the ends of the branches, white; the fruit is a berried, spherical, succulent drupe; the skin is very thin, papery, tough, white, with a very polished shining surface.—Native of the East Indies.

Humble Plant. See *Mimosa*.

Humulus; a genus of the class Diœcia, order Pentandria.—**GENERIC CHARACTER.** *Male Calix*: perianth five-leaved; leaflets oblong, concave, blunt. *Corolla*: none. *Stamina*: filamenta five, capillary, very short; antheræ oblong. *Female Calix*: involucre universal, four-parted, sharp, partial, four-leaved, ovate, eight-flowered; to each flower a perianth, one-leaved, ovate, very large, outwardly flat on one side, converging at the side. *Corolla*: none. *Pistil*: germen very small; styles two, subulate, patulous; stigmas sharp; pericarp none. *Calix*: inclosing the seed at the base. *Seed*: roundish, covered with a coat. **ESSENTIAL CHARACTER.** *Male Calix*: five-leaved. *Corolla*: none. *Female Calix*: one-leaved, spreading obliquely, entire. *Corolla*: none. *Styles*: two. *Seed*: one, within a leafed calix.—The only species is that useful plant,

1. *Humulus Lupulus*; *Hops*. Root perennial; stems weak

and twining, not climbing by tendrils, but ascending a prop, trees, shrubs, in a spiral always with the sun, that is from right to left, or from east to west by the south; this direction it has in common with *Tamus* or Black Briony, *Lonicera* or Honeysuckle, and several others; but more turn the contrary way, or from left to right, as *Phaseolus* or Kidney Beans, and several other leguminous plants, *Colvolvulus*, &c. The *Hop* stems are angular, striated, and rugged, with very minute prickles; leaves opposite, in pairs, and sometimes in threes; stipules two or four, cordate, bifid, at each joint; flowers greenish yellow; the males on branched peduncles. The Germans call hops *Hoppea*; the Dutch, *Hoppe*; the Danes and Swedes, *Humle*; the French, *Le Houblon*; the Italians, *Lupulo*; the Spaniards, *Hombrecillo*, *Hoblon*, *Lupulo*, *Lupio*, *Vidarría*; the Portuguese, *Lupulo*, *Lupara*, *Hombregilho*, *Sinoura*, *Siba*; the Russians and Slavonians, *Chmel*; the Tartarians, *Kumulak*, *Kumula*, *Umula*; and the Persians, *Kymek*. As we feel it our duty to afford every information which our limits will admit, concerning this invaluable plant, we shall first treat—*Of the choice of soil.* The hop planters esteem the richest and strongest ground the most proper; and if it be rocky within two or three feet of the surface, the hops will prosper well; though they will not thrive on a stiff clay, or spongy wet land. The Kentish planters account new land best for hops: they plant their hop-gardens with apple-trees at a large distance, and with cherry-trees between; so that when the land has done its best for hops, which they calculate will be at the end of ten years, the trees may begin to bear. The cherry-trees last about thirty years; and by the time the apple-trees become large, they cut down the cherry-trees. As to the *situation* of a hop-ground, one that inclines to the south or west is the most eligible; but if it be exposed to the south-east or north-west winds, there should be a shelter of some trees at a distance, because the north-east winds are apt to nip the tender shoots in the spring; and the south-west winds frequently break and blow down the poles at the latter end of the summer, and very much endanger the hops. In the winter-time provide your soil and manure for the hop-ground against the following spring. If the dung be rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your hop hills; but if it be new dung, then let it be mixed as before till the spring in the next year; for new dung is very injurious to hops. Dung of all sorts was formerly more commonly made use of than at present, especially when rotted and turned to mould, and they who have no other manure must use it; which if they do, cow's or hog's dung, or human ordure, mixed with mud, may be a proper compost, because hops delight most in a manure that is cool and moist.—*Planting.* Hops require to be planted in a situation so open as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middle of large plantations, while the outsides remain unhurt. As for the preparation of the ground for planting, it should in the preceding winter be ploughed and harrowed even: then lay upon it in heaps a good quantity of fresh rich earth, or well-rotted dung and earth mixed together, sufficient to put half a bushel in every hole, to plant the hops in, unless the natural ground be very fresh and good. The hills where the hops are to be planted should be eight or nine feet asunder, that the air may freely pass between them, for in close plantations they are very subject to what the hop-planters call the *fire-blast*. If the ground be intended to be ploughed with horses between the hills, it will be best to chequer them in squares; but if the ground be so small

that it may be done with the breast-plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made. Persons ought to be very curious in the choice of plants, as to the kind of hops; for if the garden be planted with a mixture of several sorts of hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner. The two best sorts are the White and the Grey Bind; the latter is a large square hop, more hardy, and is a more plentiful bearer, besides ripening later than the former. There is another sort of the White Bind, which ripens a week or ten days before the common; but this is tender, and a less plentiful bearer, although it has the advantage of coming first to market. But if three grounds, or three distant parts of one ground, be planted with these three sorts, there will be this convenience, that they may be picked successively as they become ripe. The sets should be five or six inches long, with three or more joints or buds on them. If there be a sort of hop you value, and would increase the plants and sets from, the superfluous binds may be laid down when the hops are tied, cutting off the tops, and burying them in the hill; or, when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set next spring. As to the seasons of planting hops, the Kentish planters most approve the months of October and March, both which sometimes succeed very well; but the sets are not to be had in October, unless it be from some ground that is to be destroyed: and there is some danger also that the sets may be rotted, if the winter prove very wet; hence March is the most usual time of procuring them, when the hops are cut and dressed. As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about, sloping, the tops meeting at the centre; they must stand even with the surface of the ground; let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it. The ground being thus planted, all that remains to be done that summer, is to keep the hills clear from weeds, and to dig up the ground about the month of May, raising a small hill round about the plants. In June you must twist the young branches or binds together into a knot; for if they are tied up to small poles the first year, in order to have a few hops from them, it will not countervail the weakening of the plants. A mixture of dung or compost being prepared for your hop-ground, the best time for laying it on, if the weather prove dry, is about Michaelmas, that the wheels of the dung-cart may not injure the hops, nor furrow the ground: if this be not done, then you will be obliged to wait till the frost has hardened the ground, so as to bear the dung-cart; and this is also the time to carry on your new poles, to recruit those that are decayed, and to be cast out every year. If you have good store of dung, the best way will be to spread it in the alleys all over the ground, and to dig it in the winter following. The quantity they will require will be forty loads to an acre, reckoning about thirty bushels to the load. If you have not dung enough to cover all the ground in one year, you may lay it on one part one year, and on the rest in another, or even a third year: for there is no occasion to dung the ground in this manner oftener than in three years. Those who have but a small quantity of dung, usually content themselves with laying on about twenty loads upon an acre every year: this they lay on the hills either about November or in the spring; which last some account the best time, when the hops are dressed, to cover them after they are cut; but if it be done at this time, the compost or dung ought to

be well rotted and fine.—*Dressing.* As to the dressing of hops, when the hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it. About the end of February, if the hops were planted the spring before, or if the ground be weak, they ought to be dressed in dry weather; but if the ground be strong and in perfection, the middle of March will be a good time; and the latter end of March or the beginning of April, if it be apt to produce over-rank binds, may be soon enough. Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds during the year preceding, and also all the young suckers, that none be left to run in the alley and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low which was left highest the preceding year. By pursuing this method, you may expect to have stronger buds, and also keep the hill in good order. In dressing those hops which have been planted the year before, you ought to cut off both the young tops and the dead suckers which have sprung up from the sets, and also to cover the stocks with a fine earth a finger's length in thickness.—*The Poling.* About the middle of April the hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill, to prevent the binds from entangling; and a space between two poles ought to be left open to the south, to admit the sun-beams. The poles ought to be in length sixteen or twenty feet, more or less, according as the ground is in strength; and great care must be taken not to overpole a young or weak ground, for that will draw the stock too much, and weaken it. If a ground be overpoled, you are not to expect a good crop from it; for the branches which bear the hops will grow very little till the binds have overreached the poles, which they cannot do when the poles are too long. Two small poles are sufficient for a ground that is young. If you wait till the sprouts or young binds are grown to the length of a foot, you will be able to make a better judgment where to place the largest poles; but if you stay till they are so long as to fall into the alleys, it will be injurious to them, because they will entangle one with another, and will not clasp about the pole readily. Maple or aspen poles are accounted the best for hops, on which they are thought to prosper, because of their warmth, or else because the climbing of the hop is assisted by the roughness of the bark. But for durability, ash or willow poles are preferable; but chesnut poles are the most durable of all. If, after the hops are grown up, you find any of them have been underpoled, taller poles may be placed near those which are too short, to receive the binds from them.—*The Tying.* As to the tying of hops, the buds that do not clasp of themselves to the nearest poles when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so closely as to hinder them from climbing up the pole. This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for, are to be plucked up; but if the ground be young, then none of these useless binds should be plucked up, but should be wrapped up together in the middle of the hill. When the binds are grown

beyond the reach of your hands, if they still forsake the poles, you must employ a stand-ladder in tying them up. Towards the latter end of May, when you have made an end of tying them, the ground must have the summer dressing, which consists in casting up some fine earth with the spade into every hill; and a month after this is done, you must hoe the alleys with a Dutch hoe, and make the hills up to a convenient size.—*Gathering.* About the middle of July hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be formed of their ripeness, by their strong scent, their hardness, and the brownish colour of their seeds. When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage, by breaking the branches and bruising and discolouring the hops; and it is very well known, that hops picked green and bright, will sell for a third more than those which are discoloured and brown. The most convenient way of picking them is into a long square frame of wood, called a *bin*, with a cloth hanging on tenter-hooks within it, to receive the hops as they are picked. The frame is composed of four pieces of wood joined together, supported by four legs, with a prop at each end to bear up another long piece of wood, placed at a convenient height over the middle of the bin; this serves to lay the poles upon which are to be picked. This bin is commonly eight feet long, and three feet broad; two poles may be laid on it at a time, and six or eight persons may work at it, three or four on each side. It will be best to begin to pick the hops on the east or north side of your ground, if you can do it conveniently, which will prevent the south-west wind from breaking into your garden. Having made choice of a plot of ground containing eleven hills square, place the bin upon the hill which is in the centre, having five hills on each side; and when these hills are picked, remove the bin into another piece of ground of the same extent, and so proceed till the whole hop-ground is finished. When the poles are drawn up to be picked, you must take care not to cut the binds too near the hills, especially when the hops are green, because that will make the sap flow excessively. The hops must be picked very clean, that is, free from leaves and stalks; and, as there shall be occasion, two or three times in the day, the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the kiln, or oast, in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured. In hot weather no more poles should be drawn than can be picked in an hour; and they should, if possible, be gathered in fair weather, when the hops are dry, which will save some expense in firing, and preserve their colour better than when they are dried. The crop of hops being thus bestowed, you are to reserve the poles against another year. They should be laid up in a shed, with the haulm first stripped off from them; but if you have no shed, set up three poles in the form of a triangle, or six poles, if you please, wide at bottom; and having fixed them in the ground, and bound them together at the top, set the rest of your poles about them; and being thus disposed, those on the outside only will be exposed to the injuries of the weather, for all the inner poles will be kept dry except at the top, whereas if they were on the ground, they would receive more damage in a fortnight than by their standing all the rest of the year.—*Drying.* The best method of drying hops is with charcoal on an oast, or kiln, covered with haircloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or bricklayer, in those countries where hops grow

or malt is made, knows how to build them. The kiln ought to be square, and may be of ten, twelve, fourteen, or sixteen feet over at the top, where the hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the beguels of the steddle where the fire is kept; thus, if the kiln be twelve feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionably in other dimensions. The hops must be spread even upon the oast, a foot thick or more, if the depth of the curb will allow it; but care should be taken not to overload the oast, if the hops be green or wet. The oast ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the hops, nor must it be suffered to sink or slacken, but rather be increased till the hops be nearly dried, lest the moisture or sweat which the fire has raised fall back or discolour them. When they have lain about nine hours, they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried, by the brittleness of the stalks and the easy falling of the hop-leaves. It is found by experience, that the turning of hops, though it be after the most easy and best manner, is not only an injury and waste to the hops, but also an expense of fuel and time, because they require as much fuel and as long a time to dry a small quantity by turning them, as a large one. Now this may be prevented by having a cover, to be lowered down or raised at pleasure, to the upper bed whereon the hops lie. This cover may also be tinned, by nailing single tin plates over the face of it; so that when the hops begin to dry, and are ready to turn, that is, when the greatest part of their moisture is evaporated, then the cover may be let down within a foot or less of the hops, like a reverberatory, which will reflect the heat upon them, so that the top will soon be as dry as the lowermost, and every hop be equally dried.—*Bagging.* As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately they will powder, but if they lie awhile, (and the longer they lie the better, provided they be covered close with blankets to secure them from the air,) they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep. The common method of bagging is as follows: they have a hole made in an upper floor, either round or square, large enough to receive a hop-bag, which consists of four ells and a half of ell-wide cloth, and also contains ordinarily two hundred and a half of hops; they tie a handful of hops in each low corner of the bag, to serve as handles to it; and they fasten the mouth of the bag so placed that the hoop may rest upon the edges of the hole. Then he that is to tread the hops down into the bag, treads the hops on every side, another person continually putting them in as he treads them, till the bag is full; which being well filled and trodden, they unrip the fastening of the bag to the hoops, and let it down, and close up the mouth of the bag, tying up a handful of hops in each corner of the mouth, as was done in the lower part. When hops are thus packed, after being well dried, and laid up in a dry place, they will keep good several years; but care must be taken that they be neither destroyed nor spoiled by the mice making their nests in them. In order to have hops of a good quality, 1st, They ought to be ripe before they are gathered, and in becoming so they pass from a green to a rich yellow colour. 2dly, They ought to grow on

a soil that, instead of enlarging the size of the hop, grows them full of farina, or, as the country people call it, condition. 3dly, They ought to be very much, but slowly dried, and then packed for market in the thickest covering that can be found, to preserve their strength. The colour of hops which hang till they are ripe, can never be so beautiful as if they were gathered green, for they are generally bruised by the equinoctial winds; but the quality of their bitter is of a superior flavour, goes further, and will never deceive in brewing; they will also keep good, when full dried, many years.— Having detailed the practice of the Kentish Hop-planter, we proceed generally to notice those which are of any importance in other countries. Though Mr. Miller mentions only three varieties of the hop, yet in Surry they have what they call the Orchard Hop, which bears a long square strobile, and is perhaps the same with Mr. Miller's first sort. The Streaked Bind; two or three varieties of White Bind; smooth and rough-Red Bind. The most esteemed are the Streaked, and the White Bind; the smooth Red is of little value; and as to the last, it is generally eradicated whenever it appears. The White Canterbury Bind is mostly in use. The Golden Hop, with a white bind, which is probably the same with Mr. Miller's Oval Hop, ripens later than the other, and therefore on that account may be useful to the planter. There is also the Cluster Hop, produced from a White Bind, but having the hops growing more in clusters than the others. The Streaked Bind is a desirable hop, for a part at least of a plantation, being early, of a pleasant flavour, and generally of a good size. As to the term Garlick, it is not appropriate to any one variety; for they will all acquire that sort of smell from distemper. In Surry they have not the practice of planting cherry or apple-trees as in Kent. About Atton they generally plant their hops six feet square; but about Farnham they plant much nearer: the superiority of their soil enables them to do this with success; but in blighted years they suffer more than the Atton planters, the circulation of air being much obstructed by the closeness of the hills. In Worcestershire, the Red, Green, and White Hop, are cultivated. A difference in the method of cultivation, is probably the real source of these distinctions. Two sorts, however, are in particular esteem both with the planter and merchant: the Golden Vine, brought from the neighbourhood of Canterbury; and the Mathan White, the name of which denotes it to be a native of this plantation, and of the parish of that name. The most hardy, and that which will flourish with the least attention, and is least liable to suffer from the seasons, is the Red; which is perhaps the original stock. The next is the Green, which is also the most productive. The tenderest, though at the same time the most valuable, is the White. The plantations of Worcestershire, are principally to the west of the Severn, increasing as they approach the banks of the Teame, and the confines of Herefordshire. The situations preferred are, a gentle descent, with a south, south-west, or western exposure, screened at a distance, to the north and east, by high ground, or plantations of timber, but not so as to prevent a free ventilation: the soil, a deep loamy land, or strong clay, after it has been thoroughly limed and manured; but, above all, a boggy soil, when completely drained, and duly meliorated, is said to produce the best hops. When meadow or pasture land is broke up for this purpose, it is either dug, or, the sward being first pared thinly off by the paring plough, it is buried by the furrow plough working full ten inches deep. Old tillage, when converted into hop-grounds, requires to be very completely cleared of weeds; to be thoroughly manured, and to have the ridges or lands

entirely levelled. The different manners in which they are worked, are the tump and the ploughed grounds; the former by hand, and the latter by plough: the first are laid out in the quincunx form, each tump or hill being at the distance of from five to seven feet from the centre of the other. On these, the distance between the stocks is from three to four feet; that between the rows, from seven to nine; the greater or lesser space always being ploughed, as the land is either richer or poorer. In the ploughed, if the circumstances of the ground will admit of it, the rows run mostly north and south, with a view to admit the sun more generally when it has most force; but it should be long and narrow, its greatest length extending east and west, which direction is to be preferred, for receiving the morning sun, by which means the chills of the night are soonest dissipated. The sets are procured from the sets or roots of the stocks, at the annual time of dressing, in the latter end of March or beginning of April. They must have two joints each, the roots striking from that in the ground, and the vine shooting from that above: four are planted to a stock, at the distance of about four or six inches from each other, all inclining or pointing, so as to meet together in the centre. Two methods are here observed in planting young hop-grounds. The first and most general is, to plant the sets on the situation in which they are to remain, immediately after they are parted from the old stocks. In the second, the sets are planted in nurseries, in rows about three inches asunder, with about five or six inches between the rows; here they grow till the month of October, when they are transplanted into the hop-ground. Under this latter management, if the roots be good, one will be sufficient for a stock. In removing them, great care is taken to make the opening to receive them so large as not to confine the roots. When planted from the stocks, a hole made with a peg to place them in, is all that is required. The nursery has certainly great advantage; besides the saving of a considerable expense, where the sets are to be purchased, the land may be worked through the summer, to prepare it for the plantation. During the first year, the grounds are ploughed, hoed, or kerfed, three times: they produce no hops; but a good crop of pease, beans, cabbage, or turnips, is obtained between the rows. The second year they are poled, and yield half a crop; and the third year produce in perfection.— When they have reached this state, the management is uniformly as follows: They are gone over mostly four times with the plough or kerf at the beginning of March. The first business is to throw down the tumps and rows of the former year, and to work in the manure, previously brought on in the winter. This manure consists of fresh earth, rotten dung, or a compost of dung, earth, and lime, judiciously proportioned, according to the nature of the soil; each acre receiving not less than sixty cart loads, for a good dressing: this is repeated as the nature of the land renders it necessary. The stocks are now pruned, and the remains of the old vines and superfluous shoots are removed with the hop-knife. The second moulds up the tumps and rows; the succeeding ones complete moulding up the plants, and destroy the weeds. The tumps are formed round, flat at top, and about twenty inches in diameter, and somewhat broader at the bottom. The ploughed lands are thrown up much in the same manner as for potatoes or beans, only higher, and with more soil. The shoots begin to appear in April, and the poles are pitched at the latter end of the same month, or beginning of May. These are set two or three to a stock, at a foot distance from each other, with great regularity and exactness, and inclining a little outwards over the alleys. Some attention is necessary, in this part of the business, not to overpole

the plants, either in number or length of the poles, as it weakens them; and by drawing the vine out to too great a length, renders them less productive. About the close of this month, and at the beginning of June, women are employed to direct the vines to the poles, and tie them with dried rushes: this is continued till they are out of reach. The only care then remaining, is, to keep under weeds, and to govern the plantations occasionally, to replace any vines that may stray, and repair any damage arising from the weather. When they have reached their full growth, which is in some measure regulated by the number and length of the poles, the side-shoots put out. The method of topping the vines, to promote lateral shoots, said to be practised in other plantations, is never used in this. About the second week of September they ripen, when the hop-pulling begins. In a plentiful year it continues six weeks, more or less, according to the crop. The cribs are now placed, beginning on that part which lies most exposed to the sun, as being soonest ripe; one, two, or more, as the proprietor's plantation is large or small, and he has the convenience of kilns to dry them in. Each crib has eight or ten pickers, women and children, who, where they are industrious, and employed upon a tolerable crop, will gather from six to eight bushels a day, which about fills the sack in which they are carried green to the kiln; eight of these sacks, when dried, make about one hundred weight: but in some seasons, there is not half this quantity produced. The pickers come from the neighbouring counties, but most of them from Wales. From the cribs, the hops are conveyed to the kilns, four or five of the sacks before alluded to at a time, on a horse, and are dried as soon as possible; as they damage considerably if suffered to lie long together before they are put on in the kilns. They will heat in six or eight hours, and lose colour; to avoid which the kilns are kept constantly employed day and night. The time the hops take in drying, is from eight to twelve hours, according as they are ripe and dry. Great attention and considerable judgment are necessary in this part of the business; the whole of the year's expenses and labour, and, at times, property to some amount, being at stake on a single kiln, it is usually entrusted to those who have been long used to the practice. The general principle on which they proceed, is to begin with a very gentle fire, till warmed through; the heat is then gradually increased, and continued till the cove or fruitstalk is quite sunk and dry. They are then removed, and thrown together in a heap, in a corner of a large room appropriated to this purpose, and frequently turned from one side to the other, in order to cool them completely before they are bagged.—Their method of bagging them is as follows: a strong hoop is fastened round the mouth of the sack, which is then let down through a circular opening in the floor, made for this purpose; a few are first put in, when the man who is principal in this part of the business gets in, and by constant treading presses them down as closely as he can. A second person is employed in breaking them, that is tearing the flowers, &c. from the fruit-stalk, and throwing them into the bag as they are wanted: thus they proceed till it is full, when the mouth is loosened from the hoop, and closed, leaving at each corner of the sack a space for the hand, for the better convenience of those who are employed in carrying them. After the seasons are over, the poles are set up as before described in the Kent management.—Different opinions are entertained respecting the superiority of the tump and plough management: the former certainly has the advantage in many particulars, and is said to be cheaper, and more productive; but as it is impossible, from the present extent of the plantation, that any considerable pro-

portion can be worked in this manner, from want of hands, the inquiry is not of much consequence. The expenses of these plantations may be calculated from the following statements. As they always occupy the most valuable part of the farm, the rent cannot be set down lower than thirty-one shillings per acre, and in some instances is much higher. The acre is not to be estimated as statute measure, but after the rate of one thousand stocks to the acre, which is in general one-fifth less. The expense of manure is very heavy, as they produce none, except the ashes from the burning of the vines and leaves; so that, were justice done to the rest of the land, the greater part ought to be procured from home. The price of muck or dung is about six shillings per waggon-load, or three shillings per ton, (when purchased from stables where the horses are plentifully fed with corn, it is higher in proportion,) and is frequently to be fetched eight or ten miles. The hop-grounds are sometimes worked through the several seasons, as they are termed, at a fixed price, which is from fifteen to twenty shillings per acre, according to the differing qualities of soil. The seasons are four, and thus divided:—throwing down and cutting; spreading and pitching poles; kerfing and tumping; and stripping and piling poles. Sometimes the workmen agree for a shilling a day, with drink; or some parts are taken by the acre, as pitching poles, three shillings; stripping and piling, two shillings and sixpence, to three shillings and sixpence. The women employed to tie the vines, receive sixpence per day, with two quarts of drink; or they take them by the year, at three shillings, or three shillings and sixpence per acre. The hop-pullers receive from sixpence to eightpence per day; with a pint of thickened milk, or something similar, every morning for breakfast; two quarts of drink per day, and two dinners every week. The coal, which is pit coal charred, employed to dry them, is also an expensive article, and is principally brought from Pinsax in Worcestershire, at a distance of several miles from some of the plantations, where it costs twopence-halfpenny or threepence per bushel, twenty-eight of which make a ton; two of which tons will be consumed in drying a ton of hops. The drier is paid from twelve shillings to twenty-one shillings per week, varying according to the number of kilns he has to attend; his meat and drink is also provided for him. The person who has the management of the bagging is paid four pence per hundred-weight, exclusive of his assistant. There are different articles used for bagging; the Lubecks, and a sort of cloth manufactured at Dudley in this county, are most in use, particularly the latter. The price varies according to the demand. The Lubecks are dearest; they cost in general from twenty-eight to thirty-four shillings per piece, and are thirty-six yards long, and about thirty-one inches wide. The Dudleys cost from twenty-two to thirty-two shillings, and are of the same dimensions, each piece making eight sacks, four yards and three quarters long.—The culture of hops at Hedingham castle in Essex, is perhaps as good as in any part of England; though the quality of those produced at Farnham in Surry is thought by some to be superior. At the former place there are fifty-five or fifty-six contiguous acres, remarkable for yielding an almost certain crop. The soil is a moory marsh, improved into a rich loam on the surface. They are persuaded here that hops succeed better in very large plantations than in small ones; and observe, that the outside parts of their contiguous acres do not answer equally well with the more central divisions. If, therefore, a man increase his hop-ground, it should not be in distinct plantations, but united to what he had before. In Essex they are too apt to use long poles, even such as are two rods in

length, and thirteen inches round at bottom, costing three pounds per hundred. To form a plantation, they fallow the land a year, ploughing it three or four times. In November they plant three sets to a hill, and a thousand hills to an acre. They put on no manure, if the ground be good; and dig it over as soon as planted, on account of its being trodden. In the second year nothing is done but keeping the ground clean, by skimming and harrowing; after Michaelmas they put on sixty loads of compost to an acre: gloves' and tailors' shreds are accounted a good dressing. In the third year, in February they cut down to the crown of the plant, or the black rind. At the end of March they pole the ground, three poles to a hill: after poling, they dig round the plants. As to the hop-grounds in Suffolk, the soil they plant upon about Stowmarket, is a black loose moor, on a gravelly bottom; very wet and boggy, lying on a dead level with the river that runs by the town; the more boggy and loose it is, the better the hops thrive, especially if the gravel be within three feet, and the neighbouring grounds rise so as to shelter them very well. In preparing for hops, they form beds sixteen feet wide, around which they dig trenches about three feet wide, and two feet, or two feet and a half deep; the earth that comes out being spread upon the beds, and the whole dug and levelled. Upon this, in March they form holes six feet asunder every way, twelve inches in diameter, and a spit deep, consequently there are three rows on each bed. Into each hole they put half a peck of very rotten dung or rich compost, scatter earth upon it, and plant seven sets in each, drawing earth enough to them afterwards to form something of a hillock. Some in the first years sow kidney-beans or common beans, or plant cabbages; but others do not reckon this a good way. It two or three weeks, according to the season, they will be fit to pole with old short poles, to which they tie all the shoots or vines, and then keep the land clean by hoeing and raking; and at Midsummer they hill them. The produce the first year is from three to one hundred-weight of hops on an acre. Manure is not always given, but amounts on an average to ten loads a year. They keep it till it would run through a sieve, which they prefer to a more putrid state. Three poles are put to each hill: they are generally of ash, and the length preferred is twenty-four feet; when a hop rises much above a pole, they set another to take the shoot, to prevent its falling, impeding the circulation of air, and entangling with the poles of other hills.—*Produce.* The charge of an acre of hop-ground, in most parts of England where hops are cultivated, is thus computed: three pounds per acre for the husbandry; four pounds for the wear of the poles; five pounds for picking and drying; one pound ten shillings for dung; one pound for rent, (though in some places they pay four or five pounds per acre yearly for the rent of the land,) and ten shillings for tythe: in all, about fifteen pounds a year. The English hop-planters, therefore, think they have but a moderate return, when the produce of an acre of hops does not sell for more than thirty pounds. They frequently have fifty, sixty, eighty, or a hundred pounds; and in a time of general scarcity, considerably more: so that, upon the whole, if the total charge of an acre of hops be computed at fifteen pounds a year, and its average produce at thirty pounds, the clear profit from an acre will be fifteen pounds a year. The quantity of hops produced on different soils in different years, varies from almost nothing, or perhaps two hundred-weight, to twenty and even twenty-four hundred-weight on an acre: but the average produce on middling soils, may be estimated at six, and, on such as are better, at seven or eight hundred-weight. Some mention nine hundred-weight, which may be occasionally produced, but ought not to be looked

upon as general. In some places the expenses on an acre of hops may be estimated at thirty pounds, including rent, taxes, &c. so that taking seven hundred-weight as the average produce, the planters must greatly lose when they sell at four guineas per hundred: but we have already seen that this article is liable to such fluctuations that the average price obtained must be much more; and indeed if it were not, the planters could not continue to cultivate it. Hops are occasionally very profitable, although extremely uncertain in their produce, which always must be very expensive. To lessen the expense of poling and the trouble of picking, it has been suggested, that planting hops in the form of an espalier might probably answer; for it is observed, when a pole falls, and another is obliged to be fixed in a lateral position, the hop always bears more by being thus trained horizontally, and hops in an espalier might be picked as forward as the planter chose, without cutting the vines. If hops also were only planted in such soils and situations as are well adapted to them, there would be a much greater probability of an efficient crop; and by this means, though the expense would not be diminished, the average profit would be increased. Savings might certainly be made in cultivating only on proper soils, where a less quantity of manure is wanted, than upon such as are congenial to this crop; or in the vicinity of great towns, where abundance of manure can be easily procured; by attention to the quality, operation, and effect of different manures, with the best time of laying them on; by uniting the business of maltster to that of hop-grower, by which the malt-office may save the expense of building an oast, or kiln, for drying them; and by other attentions, of which the hop-planter ought to be the best judge. The tythe of hops ought surely to be regulated, where the expense to the cultivator is so very considerable.—*General Observations.* It is a general opinion among the hop-planters, that the plants which bear the male flowers, or the Wild Hops, as they call them, are of no service in securing or increasing a crop; they are therefore in general cast out. It would be well, however, if some accurate experiments were made on this subject. As to the soil, there will be no doubt of hops thriving when there is good marl or chalk, or even a moist rock at bottom, with a surface of tolerably deep mould frequently manured. The best soil certainly is a strong loam; clay, and a light black loam, are both bad. In general, however, every other year is often enough to manure the hop-ground; and twenty cart-loads to each acre, a sufficient quantity. It is the common practice to lay the dung on the crown of the hill, that the winter rains may carry it down to the roots: but some spread the dung over the ground in autumn, and seldom dig it in before February. Part of it is brought to hills in the course of hilling the hops in summer, and part remains in the intervals for the nourishment of the fibres. Though, in very favourable soils, hops may be continued on the same spot at pleasure, yet it is generally advisable to break up the hop-yard entirely in twenty or thirty years, when the soil will be found in high order for almost any crops for some years after, particularly for potatoes, of which an immense burden may be produced from such ground. In the preparation for planting, and the manner of it, the practice is very various. The ground is generally ploughed and harrowed well the winter before it is intended to be planted: but that does not seem necessary; for by the time the workmen have gone over it, first to set out the hills, and then to dig the holes and plant the hops, the ground becomes so trodden as to be little the better for ploughing. A better method seems to be, to prepare the ground well the summer before, and sow it with turnips, by which means it is tho-

roughly cleaned; and early in winter, or if in autumn the better, either to pull up the turnips, or feed them off with sheep, as occasion may require, and so let it remain till the spring; and then plant the hops, and dig the ground. Sow turnips again in the ensuing summer, and, as these must be hoed twice, the young hops are cleared at the same time. When they are spent, care must be taken, if they are fed off on the ground, to do it in dry weather. Thus the land being dressed by the sheep, will not at first require so much manure. Beans also, or potatoes, may be planted the first year between the hills; and either mode will bring some profit during the very time in which the hops afford none. October is the most proper season for planting with cuttings of the last year, or nursery plants, as they are usually called. In Worcestershire, when the hop-grounds are come to perfection, it is the general practice to exclude every other growth, and trust to them alone for a return of the great expense at which they are cultivated. Under this management, those which have been uniformly attended to in their prime, and not weakened by over-poling, will continue to produce plentifully from twenty to thirty years, and in some instances much longer; care being taken to replace the stocks that accidentally decay. On the other hand, fresh grounds are generally allowed to produce the finest hops, and in the greatest abundance. The circumstance of those hops which are most in request ripening nearly all at one time, is a considerable inconvenience both to the owner and holder of the estate; as they damage so soon, whether left on the wires when ripe, or gathered, if not dried immediately. Hence it is necessary to have buildings and a number of kilns in proportion to the size of the plantations, and more hands during the season than would be otherwise wanted. Could those sorts which ripen earlier be improved, or any others introduced that do so, it would be an important acquisition. The parts necessary to perfect the seeds, are found on different plants; and as the greatest stress is laid on these, it may be proper to notice, that the practice of removing the barren stocks may be carried too far: it is an inquiry worth attending to, whether this be not the cause, in some instances, of the early decay on many grounds. In cutting hops, a necessary caution should be observed respecting such as are young, not to use the knife too freely the first year. At this age, a sufficient number of joints should be left below the knife; and if the plants are weak, it may be as well only to trim off the dead bind of the last year. Experience will best teach the planter when his hops are fit for picking. It is nevertheless better to begin too soon than too late, as the high winds which prevail towards the equinox many times produce more injury to the planter, than he would sustain by beginning a day or two before his hops were thoroughly ripe. It is the prevailing opinion that the last-picked hops will weigh heavier when dried than the first; but the experiments of Mr. Prowling of Chewton have demonstrated this to be a vulgar error. He calculates that a bushel of green hops, in a favourable year, will yield about a pound and a half in weight when dried. In Worcestershire, most of the estates which grow many hops, have plantations for raising the poles. Ash and barked oak are preferred; but willow, poplar, and alder, are also used. Where the estate does not produce a sufficiency, they are bought at the woods and coppices in the neighbourhood, at from five to fifteen shillings per hundred. Their length is from eight to eighteen and twenty feet, according to the goodness of the lands, and they last seven or eight years with care. The sets cost from two shillings to two-and-sixpence per hundred: their length is from eight to eighteen. In this county, the average of general expenses is thus calculated:

workmanship twenty-five to thirty shillings per acre; picking, drying, charcoal, sack, and duty, thirty shillings per hundred-weight. The implements used throughout this plantation are, the plough, the kerf, the spade, iron crow, and hop-knife. The plough is the common one of the district; the kerf is a large hoe, with a plate about nine inches broad and thirteen deep; the spade needs no particular description; the crow is an iron bar, about four feet and a half long, generally square at top, with a large point in the octagon form, used to make the hole in the ground for pitching the poles; the hop-knife resembles the sickle in make, an old one being often converted to this purpose by grinding off its saw-edge, and giving it a sharp one in its stead; when made for the purpose, it is something smaller. The crib and bags have been already described; the sacks, in which they are carried from the hop-ground to the kiln, are made of the same materials as the bags. In Essex the poles most esteemed are the chestnut, ash, oak, willow, and maple; all fourteen years growth from a wood, or eleven from a plantation. Mr. Boys, in his *Agricultural Survey of Kent*, enumerates the following things as necessary to a hop-ground of four or five acres. 1. An oast or kiln about sixteen feet square, costing, when substantially built and allowing stowage-room, from £150 to £200. 2nd, A set of picking baskets, about twelve in number, and a good scale-beam and weights. 3rd, A skim made with a frame like a wheelbarrow, which is also very useful for tearing up weeds on summer fallows. 4, A harrow drawn by one horse, with a small wheel in front, to go round at the ends of the plantation; and a pair of handles to be holden by the man who follows it, in order to keep it from bruising the binds. 5, An iron peeler, to make holes for the poles to be fixed in; and a hop-dog, to wrench them up.—*Diseases.* The hop-grower has many enemies to dread. A fly, similar to that which proves so fatal to turnips, attacks them on their first appearance in the spring, and sometimes entirely destroys the first shoots. It is a very small animal, which on your approaching to touch it, retreats into the ground with the nimbleness of a flea. Chalky land is much subject to them, and they seem to be produced by warm dry weather. In Surrey, a handful of dry ashes scattered over every hill is thought very serviceable in driving them away; but the Essex planters esteem it better to dung highly, that the plants may grow out of danger, for they are considered safe when they reach two feet high; they do not therefore apply any thing to stop it, thinking that a shower of rain will complete the cure. The next enemy is the fly mentioned by Mr. Miller, by which he means the long-winged fly, as the Surrey planters call it. The appearance of these vermin is dreaded as a pestilence; they are the forerunners of lice, and at last generally ruin the crop. The lice do not appear to eat, but to poison, the leaf; they are worst in thick, cloudy, hot, and moist weather. Many suppose that the rain will wash them off, but this seems to have no foundation, for they generally shelter themselves on the under side of the leaf, where no rain can touch them. Lightning seems to be their greatest enemy. These flies and lice are all aphides, some of which are winged, and others not: and the honeydew, so destructive to the hop, is their excrement; it causes their leaves to turn black, shrink, and at length fall off. Sometimes they are so infested with this distemper, and the lice united, as to perish entirely, and require to be planted anew for many hills together. Another calamity to which hops are liable is, the red blight. This seldom attacks them till they come to maturity, causing the hops to assume a reddish or rather deep yellow colour, and the leaves frequently to grow pale and sickly. When this happens, they

acquire a garlic-like smell, and ought to be picked with the greatest expedition. This disorder appears to be incident to particular lands, especially those of a light poor quality, and therefore is in all probability a natural decay, and not a blight. Dr. Withering's observations on the honey-dew deserve to be introduced to the notice of planters. He says, if the hop yards were covered with stones, the plants would be less liable to suffer from the honey-dew and otter-moth; for the honey-dew is the excrement of a species of louse, but these insects seldom increase so as to endanger the plant, unless it is in a weak condition; and the larvæ of the otter-moth at the roots, first occasion the plant to be sickly. Now when the hops grow wild in stony places, and fissures of rocks, where the moth cannot penetrate to deposit its eggs, the hop is never known to suffer from the honey-dew. Admitting this view of the disease, might not the practice of smoking the fruit plantations on the first alarm of a blight, as practised in some fruit countries, be applied here to those of hops? The other injuries to which they are liable still remain without a remedy. A free circulation of air through them, and complete draining of the land, are the only alleviations. The use of the kerf is certainly attended with one disadvantage: the person using it, in some measure defeats the intention of his own labour, as he must, in some degree at least, tread down again the soil he had just loosened; and often reset a weed which he had just before turned up: but the greater dispatch made with this implement will always secure it a preference before the spade.—*Uses.* The Society for the Encouragement of Arts, Manufactures, and Commerce, at London, offered premiums in the year 1760 for cloths made from hop-stalks or binds. The year following, Mr. Cooksey produced some specimens of cloth, and was of opinion that it would answer very well the purpose of fine sacking and coarse bagging for hops. He had kept the material too long under water; and found that at the end of six weeks or two months the binds afforded filaments sufficiently strong and fine for any purpose. In 1791, Mr. John Locket of Donnington, near Newbury in Berkshire, had the premium adjudged to him for cloth made from these stalks, or Hop-vines, as they are here called. They were cut in lengths of about two or three feet; put into a furnace in which was some lye that linen had been boiled in for bleaching; and then boiled till the rind easily separated from the stalk. When cool, they stripped so freely that children might do it; and the yield was great in proportion to the quantity of stalks. The same method was then followed as in working hemp or flax; but it is much more stubborn than either, and therefore not so well adapted for making fine cloth: the fibres are also so united with a very adhesive matter, that they do not easily separate; but for sacks and cordage, it may certainly be very serviceable. Some of it was hackled while it was wet soon after it was taken off, yet it did not separate the fibres. Carding seems to work it best, and to make it like cotton. Of the piece of cloth exhibited, the warp was hackled and the woof carded. The Swedes make a strong cloth from the stalks, which must be gathered for this purpose in autumn. The use of hops for preserving beer, and the cultivation of the plant, were introduced into England from Flanders in the middle of the sixteenth century. Ground Ivy (see *Glechoma Hederacea*) was generally used for preserving beer, before the introduction of hops. Since their introduction, many wholesome plants have undoubtedly been used as succedaneums when hops were scarce, and of course exorbitantly dear; as, the roots of Ginger and Gentian; the seeds of Coliquintida; and the herbs of Horehound, Wornwood, Broom; *Carduus Benedictus*, *Centaurea Calatropa* or Star Thistle,

Marsh-Trefoil or Buck Bean; the last of which is much recommended as a more wholesome bitter than even that extracted from hops, in the proportion of only two ounces where a pound of hops was employed. All brewers, however, are enjoined, under a severe penalty, to use no other bitters than hops in their malt liquors: but there is evident reason to conclude that this law is of no avail; so much, indeed, that we fear our readers will ask for what intent we have gone into so long a detail upon an article which bids fair to be wholly excluded from modern breweries. Those who have invested large capitals in the immense breweries of London, Dublin, and other cities, take care to cry out when the barley and hop-harvests fall short or fail; but we wish to know what concern they really have in these articles. The amazing difference between the beverage brewed in families from the materials which the law enjoins the brewers to employ, when used in the same proportions, and with all the advantages of preparing larger quantities, and of better apparatus, on the brewers' side, is universally known to be in favour of brewing at home. What then is the cause of an effect so opposite to what the public have a right to expect? The cause has been traced to the employment of foreign, and, we fear, even of noxious drugs. They explore, as Mr. Gifford observes, the East Indies for the *Menispermum Coculus*, or *Coculus Indicus*; this is their substitute for malt. The West Indies furnishes them with Quassia, &c. and Spain with liquorice. These two last might be tolerated, but they are not the proper materials for producing the wholesome beverage which used to regale our forefathers. The former ingredient is used in the East Indies, by pounding the berries into a kind of paste, which, cast into water, intoxicates the fish so that they are caught by the hand. From this circumstance some conclusion may be formed as to its properties and effects when introduced into the human frame. Not content with these, that most abominable of all abominations, Tobacco, is notoriously used as a substitute for the hop; and green vitriol, with other poisons too numerous to name, are added, to mature the deleterious mixture. Hence it is that the poor mechanic is drawn into habitual inebriation: he cannot slake his thirst, without causing it to return with greater force at very short intervals; unconscious of the cause, he repeats the draught, and the consequences are disease, and premature, and even sudden, death. Half the apoplexies, says an eminent physician, in the British metropolis, arise not so much from drinking spirits, as from the noxious ingredients, particularly green vitriol, administered in the malt liquors there consumed. When will the strong arm of power put a stop to these iniquities? when will our rulers extend it, to protect the health, morals, and happiness of the community, and arrest the deadly ravages of those unprincipled villains, who wallow in ill-gotten wealth for a few years, and then bequeath immense revenues for their profuse descendants to scatter to the winds?—*Medical Properties.* A decoction of the roots of hops, from one to two ounces; or an extract from them, to the quantity of twenty or thirty grains; is said to be sudorific, answering the purpose of Sarsaparilla. Both these and the strobiles have a balsamic principle, and are thought to be serviceable in removing obstructions, correcting the viscosity of the lymph, opening the pores of the skin, and cleansing the kidneys. The young shoots are eaten early in the spring as Asparagus, and are sold under the name of Hop-tops, which are said to be diuretic, and good for the scurvy, taken by infusion. Hill says, that a decoction of fresh-gathered hops is good against the jaundice: and adds, that the powder of hops dried in an oven has been often known to cure agues, but admits that upon this last there is no absolute dependence.

The heads and tendrils are used to purify the blood in the scurvy, and most cutaneous diseases; decoctions of the flowers and syrups thereof are efficacious in pestilential fevers; juleps and apozems were formerly made with hops for hypochondriacal and hysterical affections, and to promote the menses. A pillow stuffed with hops, and laid under the head, is said to promote sleep in fevers attended with a delirium. Culpeper concurs in all that has been above advanced concerning the virtues of this plant; and adds, that they help to cure the *French disease*, and that the decoction of the flowers and tops do help to expel *poison* that any one hath drank: at last he concludes with, "Mars owns the plant, and then Dr. Reason will tell you how it performs these actions." It may be because we have not the happiness of being so intimate with the last-mentioned gentleman as Master Culpeper was, but he certainly never told *us* any such thing. We have before insisted that immediate application to a regular surgeon was the only safe course which those tainted with venereal infection could take, and here beg leave to repeat that advice. The latter part of Culpeper's assertion is too absurd to need confutation.

Hura; a genus of the class Monœcia, order Monadelphia. —GENERIC CHARACTER. *Male flowers*. *Calix*: ament from the divarication of the branches, oblong, drooping, covered with sessile, spreading florets; scales oblong; perianth within each scale of the ament, cylindric, two-leaved, truncate, very short. *Corolla*: none. *Stamina*: filament cylindric, a little longer than the calix, peltate at the tip, rigid, below the tip twice or thrice verticelled, with tubercles; antheræ two, immersed in each tubercle, oval, bifid. *Female flowers in the same plant*. *Calix*: perianth one-leaved, cylindric, furrowed, truncate, quite entire, closely surrounding the germen. *Corolla*: none. *Pistil*: germen roundish within the calix; style cylindric, long; stigma large, funnel-shaped, plano-convex, coloured, twelve-cleft, blunt, equal. *Pericarp*: woody, orbiculate or globular-flatted, torose, with twelve furrows, twelve-celled; cells dissilient, crescent-shaped, with an elastic dagger-point at the end. *Seeds*: solitary, compressed, suborbiculate, large. ESSENTIAL CHARACTER. *Male*. Ament imbricated; perianth truncated. *Corolla*: none; filament cylindrical, peltate at the tip, surrounded by very many antheræ in pairs. *Female Calix* and *Corolla*: none. *Style*: funnel-form. *Stigma*: twelve-cleft. *Capsule*: twelve-celled. *Seed*: one.—The only known species is,

1. *Hura Crepitans*; *Sand Box-tree*. It rises with a soft woody stem to the height of twenty-four feet, dividing into many branches, which abound with a milky juice, and have scars in their bark where the leaves have fallen off. The branches are garnished with heart-shaped leaves; the biggest eleven inches long, and nine broad in the middle; indented on their edges, having a prominent midrib with several transverse veins from that to the sides, which are alternate: they stand upon long slender footstalks. The male flowers come out from between the leaves, upon peduncles which are three inches long; they are formed into a close spike or catkin, forming a column, lying over each other like the scales of a fish. The fruit is very curious in its structure; and the tree, when it grows well, is very spreading and shady. It sometimes attains the height of thirty-five or forty feet, and casts a shade of sixty feet diameter. But owing to the rapidity of its vegetation, its parts are of so loose a texture, that a loud clap of thunder, or a sudden gust of wind, frequently causes the largest boughs to snap asunder. Linneus says the wood is fit for joints and spars; which Long denies, declaring it fit only for fuel. Linneus also remarks, that if the juice get into the eyes

it will bring on blindness after the eighth day; but we do not know whether this be accurate or not. The roasted seeds, according to Hernandez, will purge and vomit. Browne tasted one of them, which at first appeared to be both mild and pleasant; but it soon began to warm and scald both his palate and throat, on which account he judged it to be an improper purgative. This tree is propagated by seeds, which should be sown early in the spring, in pots filled with light rich earth, and plunged into a hot-bed of tanner's bark. If the seeds be fresh, the plants will appear in about five or six weeks after they are sown. As the plants will advance very fast where due care is taken of them, they should have a large share of fresh air in warm weather, to prevent their drawing up weak. When about two inches high, they should be transplanted each into a separate small pot, filled with light rich earth, and again plunged into the hot-bed of tanner's bark, being careful to shade them from the heat of the sun, until they have taken new root; after which they must have free air admitted to them by raising the glasses in proportion to the warmth of the season, and gently watering them. When the plants have filled these small pots with their roots, they must be shaken out of them, and their roots trimmed, and then placed in larger pots, filled with the same kind of rich earth, and plunged again in the hot-bed, where they may remain till Michaelmas, provided the plants have room without touching the glasses. At Michaelmas, they require to be removed into the bark-stove, and plunged into the warmest part thereof: during the winter season they must be sparingly watered, for as the plants have succulent stalks, much water will rot them; and if not kept very warm, they will not live in this country, the open air of which they cannot endure even in the warmest part of the year. The ample leaves of this plant, which are of a beautiful green colour, afford an agreeable variety among other tender exotics in the stove. It grows naturally in the Spanish West Indies, from whence it has been introduced into the British colonies; and is much cultivated in Jamaica for its beauty, and the fine shade it yields. In those climates it prefers a deep rich soil, and thrives best near water. It is become pretty common in the English gardens, where it has grown twelve or fourteen feet high, producing flowers, but no fruit that we have ever yet heard of.

Hyacinthus; a genus of the class Hexandria, order Monogynia. —GENERIC CHARACTER. *Calix*: none. *Corolla*: monopetalous, campanulate; border six-cleft, reflex; nectary three honied pores at the tip of the germen. *Stamina*: filamenta six, awl-shaped, shorter; antheræ converging. *Pistil*: germen superior, round, three-cornered, three-furrowed; style simple, shorter than the corolla; stigma obtuse. *Pericarp*: capsule roundish, three-sided, three-celled, three-valved. *Seeds*: in pairs, generally roundish. ESSENTIAL CHARACTER. Corolla bell-shaped, with three honied pores by the germen.—The species are,

1. *Hyacinthus Nonscriptus*; *Common Hyacinth*, or *Harebells*. Corollas tubular, bell-shaped, six-parted; segments rolled back; bractes in pairs; root a roundish bulb, the size of a nutmeg; scape from six inches to a foot in height, upright, round, smooth, and solid, bowed down when it begins to flower; leaves four, six, or sometimes more, only half the length of the scape, and about half an inch broad, keeled, hollow, smooth, shining, grass green, flaccid, bending downwards, ending in an acute point; flowers in a long raceme or spike, from eight to twelve, often more, all pointing one way, pedicelled, pendulous, sweet smelling, of a blue or violet colour, varying to white and flesh-coloured, six-parted to the very base. The honied pores which Linneus gives as

the essential character of the genus, are not discoverable in this species: this has led Dr. Withering to wish the plant had been arranged under the genus *Scilla*; in which Dr. Stokes concurs, thinking it has more of the habit and even structure of *Scilla* than of *Hyacinthus*. The drooping of the flowers distinguishes it from *Scilla Campanulata*, a plant often found in our gardens, flowering at the same time. The fresh root is poisonous, but may be converted into starch. Gerarde says that they are full of a slimy glueish juice, which serves to set feathers upon arrows instead of glue, and to paste books with, and that they make the best starch next to Wake-robin roots. Hill informs us also, that the root is full of a slimy juice, and that a decoction of it operates by urine. Dried and reduced to powder, it is of a balsamic and somewhat styptic nature. The virtues of it are little known, but there are few of the remedies employed for the cure of that weakening complaint, the Whites, equal to this; the dose however ought not to exceed three grains. The fanciful term *Nonscriptus* was applied to this plant by Dodonæus, because it has not the *Ai, Ai*, on the petals; hence it is not the *Hyacinthus Poeticus*. Our old botanists name it *Anglicus*, and English *Hyacinth*, from its extreme commonness in many parts of our island. Gerarde calls it *Blue Harebells*, or English *Jacinth*; and it is "the azure Harebell" mentioned in Shakespeare's *Cymbeline*. The French call it *Jacinte des Bois*; and the Germans, *Niederlandische*, or *Englische Hyacinthe*. It adorns our woods, coppices, and hedge-rows with its flowers in the spring months, and is very common with the blue flowers: carnation and white flowers are not so common. Gerarde found them near Colchester in Essex: at Southfleet, near Gravesend; and in the neighbourhood of Canterbury, in Kent; Bath, in Somersetshire; and Warrington, in Lancashire. Ray observed the white flowers at Scadbury park in Kent, and Dr. Stokes near Worcester. It is also found in the inclosures about Streatham and other places in Surry: it is seldom admitted into gardens. Mr. Curtis remarks that the seeds are not ripened till the end of the year, and that on being sown, they did not rise till the second year.—Native of France, Flanders, Switzerland, Italy, Spain, and Persia. See the third species.

2. *Hyacinthus Cernuus*; *Bending Hyacinth*. Corollas bell-shaped, swelling at the base, six-parted; raceme drooping: this resembles the preceding, but is smaller. The raceme is more nodding; the corollas flesh-coloured, not blue: the corolla swells out at the base, which is by no means the case in the first species. Miller, Ray, and Caspar Bauhin, however, thought it a variety, differing principally in having the flowers of a blueish peach colour. That which Mr. Miller absurdly calls *Hyacinthus Utrique Floribus*, does indeed seem to be a variety of this species. It has blue flowers disposed on every side of the stalk, which rises about nine inches high. The thyrses of flowers is large when the roots are strong. He adds, that it is a native of Italy, and was formerly preserved in gardens, but having been neglected for the fine varieties of the Eastern hyacinths, is now become scarce; which is the case with many old favourites, who are cast out to make room for new comers. It is seldom cultivated in gardens.—Native of Spain. See the next species.

3. *Hyacinthus Serotinus*; *Late-flowering Hyacinth*. Outer petals almost distinct, inner co-adunate; flowers in a raceme all pointing the same way, drooping a little, each on a short peduncle, with an awl-shaped bracte at the base; corolla of a dull greenish red colour. When the flowers first appear, of a light, but, according to Miller, fading to a worn-out purple colour. Gerarde describes them as of a very dusky colour, as it were mixed with purple, yellow, and

green; without any smell. Parkinson, who calls it Spanish Dun-coloured *Jacinth*, says it is of a purplish colour, with some white and green as it were mixed among it. Ray observes, that the plants which he raised from seed of the same root, varied in the colour of their flowers, some being dusky, and others almost green. It flowers in June, later than the other hyacinths, and hence Clusius called it *Serotinus*.—Native of Spain, near Aranjuez; and of Barbary, in the neighbourhood of Fez and Morocco. This, as well as the first, second, and fifth species, are seldom admitted into gardens, having been almost totally neglected since the introduction of the Eastern hyacinths. Those, however, who wish to preserve them, may effect it without much trouble, for their roots propagate plentifully in any soil or situation, and only require to be taken up every second or third year after the leaves decay, and to replant them in the following autumn: for if permitted to remain longer in the ground, their roots will multiply to such a degree as to render their flowers very small and weak. All the species may be increased, either by seeds or offsets from the old bulbs, but it is only practised in these four species.

4. *Hyacinthus Viridis*. The outermost segments of the corollas, awl-shaped and very long. This is of the same stature with the next species, but the corolla is green.—Native of the Cape of Good Hope.

5. *Hyacinthus Amethystinus*; *Amethyst-coloured Hyacinth*. Corollas bell-shaped, half six-cleft, cylindrical at the base. This has a smaller-flower; the petals are cut half their length, and are reflex at the brim; the lower part is cylindrical, a little swelling at the base, and of a deeper blue. The root, according to Clusius, is the size of a small olive, covered with a brown skin; leaves five or six, longer and narrower than in the first sort, striated and keeled, lying mostly on the ground. Scape slender, a long span in height, round, smooth, glaucous, having six or seven flowers at top; according to Ray, sometimes twelve or more, nodding on pedicels half an inch in length; they are of a bright blue, without any scent. Most of them, says Parkinson, have white stripes and edges, and they vary to pure white, and a fine decayed pale red colour, with deeper-coloured veins running along the three outer segments. Mr. Miller says, it was formerly called *Coventry Blue Hyacinth* by the gardeners.—Native of Spain, Italy, and Russia. See the third species.

6. *Hyacinthus Revolutus*; *Wave-leaved Hyacinthus*. Corollas bell-shaped, six-parted, revolute; leaves oblong, waved.—Native of the Cape of Good Hope.

7. *Hyacinthus Orientalis*; *Garden Hyacinth*. Corollas funnel-form, half six-cleft, swelling at the base, with two small bractes under each pedicel. It has a large coated bulb, viscid, and of a sweetish taste, from the bottom of which spring the roots, which are long round fibres of a middling thickness; from the middle of it rises a single naked stem or scape, and from the top six or seven more leaves, which are broadish, keeled, pale green at bottom, but of a darker green towards the end. From the middle of the scape, to the top, come out the flowers, one above another, not pointing the same way, as in the Harebell, but standing on different sides of the stalks, three, four, five, and up to twelve in number, each nodding on pedicels, half an inch in length, usually of a very dark green colour, and having a pair of small bractes at the base, where it swells or bellies out, and at the top the segments are turned back a little. These flowers have a very sweet smell, and are much valued for the variety of their colours, as pure white, white tinged with blue, all shades of blue, even to the dark violet, and all shades of red purple, from the faint blush to the deep red:

they are also sometimes yellow. Culture and great attention have also brought these plants to be very strong, and their flowers to be very large and double. It seems to have been brought into England some time in the sixteenth century, yet the double flowers were not much esteemed, long after the hyacinth had attracted the attention of the florists. The beauty of this celebrated flower, was then supposed to consist in the regularity and equality of the petals, and the uniformity of the colours. The first double flower, cultivated by Peter Voorhelm, was named Mary, which variety is lost, as well as the two next that were produced: the King of Great Britain, which is now looked upon as the oldest double hyacinth, appeared about the beginning of the present century; it was greatly preferred to all the flowers then known, and the price rose to above a thousand florins. From that time the greatest attention has been paid at Haarlem, to the raising and cultivation of this elegant flower; and such has been the rage for it, that nearly two hundred pounds sterling has been given for a single root. The gardeners there distinguish nearly two thousand hyacinths by name, and generally publish catalogues of them from year to year. New varieties are annually produced, and whole acres together are covered with this flower, in the circuit of that town alone. The hyacinths are distributed into classes, from their colours; the principal of which are, blue, red, purple and white, with some yellow; and they are subdivided from the shades of each colour: as, of the blues; deep blue, violet blue, blue purple, porcelain blue, agate blue, sky blue, French gray: of the reds; deep or full red, rose-coloured, carnation &c.: also from the mixtures of different colours or shades; as light blue, with a deep blue or purple eye; light-red, with a deep red eye; white, with a rose-coloured, blue, purple, or yellow eye; white and red of different shades; and blue, violet, and purple, of different shades mixed; also yellow with a purple eye, &c. Some have their petals striped with a paler or deeper colour; and all these varieties are found both in single and double flowers; but the latter only are now much regarded among florists, unless it be for producing seeds, by which alone they can procure new varieties. The principal properties of a fine double hyacinth are the following. 1. The stalk should be tall, strong, and upright; the flowers (or bells, as the florists term them,) sufficiently numerous, each suspended by a short strong peduncle, in an horizontal position; the whole having a compact pyramidal form, with the crown, or uppermost flower, perfectly erect. 2. The flowers large, well filled with broad bold petals; appearing rather convex than flat or hollow, extending to the middle of the stalk. 3. The plain colours, clear and bright; strong, not pale; mixed colours elegantly blended. It is a native of the Levant, very abundant about Aleppo and Bagdat, where it flowers in February: in our climate, it flowers in March and April. The method of raising these flowers from seed, is, first, in the middle or latter end of August to provide good seed, saved from good semi-double, or such single flowers as are large, and have good properties; then procure some square shallow boxes or pots, with holes to let off the moisture; fill them with fresh, light, sandy soil; lay the surface level, and sow the seeds on it as equally as possible; cover them half an inch thick with the same light earth; place them so as to enjoy the morning sun, until the latter part of September, then remove them into a warmer situation, and towards the end of October place them under a common hot-bed frame to protect them from hard frosts during the winter and spring months, but admitting the air in mild weather. The young plants will appear at the end of February, or begin-

ning of March, and must be carefully protected from frost; but never covered except at night, or in very rough weather, for covering causes them to grow up tall and slender, and prevents the growth of the roots. In the middle of April, during fine weather, the boxes may be removed out of the frame, and placed in a warm situation, observing to water them in dry weather, and to keep them very clean from weeds. At the beginning of May, the boxes should be removed into a cooler situation, to avoid the heat of the summer, which they cannot sustain. They must not be placed under the dripping of trees, nor yet be watered after the blades have decayed, for that would rot their roots: weeding them should be diligently performed. At the end of August, sift a little light rich earth over the boxes, and again remove them into a warmer situation, and treat them, during the winter, spring, and summer months, as before directed; about the middle of the next August, prepare a bed of light, rich, sandy soil, in proportion to the quantity of seedling plants. Having levelled the surface very even, take the earth from the boxes in which your plants were raised, into a sieve, in order to obtain all the roots, which, if they have grown well, will be about the thickness of a small quill; these roots should be placed upon the bed, about two or three inches asunder, observing to set the bottom part of their roots downwards, and cover them over, two inches thick, with the same light earth: but as it may be impossible to get all the small roots out of the earth in the boxes, let it be spread out evenly upon another bed, and covered with light earth, by which method all the roots, however small, will be saved. These beds must be arched over with hoops, and in very hard frosty weather be covered with mats, to protect them from frost; and in the spring, when the green leaves are above ground, if the weather should be very dry, you must refresh them sparingly with water, for nothing is more injurious to these bulbs than too much moisture. During summer, the beds must be constantly kept clear from weeds, but the plants must have no water after the blades are decayed. In autumn, stir the surface of the bed with a very short hand-fork, taking great care not to thrust it so deep as the roots, which, if injured, generally perish soon after. Then sift a little fresh, light, rich earth over the bed, about an inch thick, or somewhat more, and again cover them in winter, as before directed. In this bed, the roots may continue two years, observing to treat them both in summer and winter as before; then the third year the roots should be carefully taken up, a little before the leaves decay, relaying them horizontally three weeks in the ground to ripen, after which they may be kept out of the ground till the end of August, when they should be planted into new beds prepared as before, placing them at the distance of six inches asunder. Here the roots may remain till they flower, during which time they should be treated as before, with this difference only, that instead of covering them with mats in the winter, the surface of the ground should be covered with tanner's bark. When their flowers begin to shew themselves, mark all such as appear to have good properties, by thrusting down a small stick near each root, which roots, at the time of taking up, should be selected, and replanted by themselves. When the green leaves begin to decay, take up the roots, raise a bed of light earth into a ridge, the better to shoot off the moisture; laying the roots into the earth again in an horizontal position, leaving the green leaves hanging out of the ground from the roots, whereby the great moisture contained in their very succulent leaves and flower-stalks, may be exhaled, and prevented from returning to the roots, which is often the cause of their rotting after they are

out of the ground. In this ridge the roots should remain until the leaves are quite dried off, when they must be taken up, and after being cleared of all manner of filth, which would be hurtful to them, they must be laid up in boxes, where they may be preserved dry until September, which is the proper season for planting them again.—*Of the Dutch Hyacinths.* Want of skill alone, in Mr. Miller's opinion, is the cause of the frequent failure which English florists meet with in the culture of these noble flowers; for he thinks they may thrive at least nearly as well in England as in Holland. The soil in which they succeed best is a light, sandy, fresh, rich earth, composed half of fresh earth, taken to the depth of eight or nine inches, with the sward off the surface of a common pasture-land, which is usually a sandy loam: to this a fourth part of sea-sand, and another of rotten cow-dung, which should be mixed well together, cast into a heap that the turf may rot, and turned over once every six weeks or two months. If this compost be made two years before it is used, it will be much better: but if you must use it sooner, it should be the oftener turned, that the parts may the better unite. This soil should be laid to the depth of two feet on the beds designed for the hyacinths; and if you lay a little rotten cow-dung or tanner's bark at the bottom, which may be within the reach of the fibres, but should on no account touch the bulb, it will be better. If the soil be very wet where these beds are made, raise them ten or twelve inches above the surface of the ground; if dry, not above three or four inches. Prepare the beds as follows: take all the former old earth out of the bed to the depth you intend, which should be nearly three feet; spread some rotten cow-dung or tan in the bottom, six inches thick, and level. Upon this lay the above compost two feet deep, levelling it very even. Then score out the distances for the roots, which should be eight inches square, in straight rows each way: place your roots exactly in the squares, observing to set the bottom part downwards; then cover the roots six inches deep with the same prepared earth, taking care not to displace any of the roots; and making the tops of the beds a little rounding, to shoot off the wet, it will be of service in moist ground, provided the middle of the beds be not made too high, which is a fault the other way. The best season for planting these roots is the middle or latter end of September, according to the earliness or lateness of the season; but it is not advisable to plant them when the ground is very dry, unless there be a prospect of rain, for if the dry weather continue long after they are planted, the roots will acquire a mouldiness which will certainly destroy them. The beds will require no further care till the severe frost sets in; then let rotten tan be spread over them to the depth of four inches: and if the alleys on each side of the bed be filled up either with rotten tan, dung, or sand, it will keep the frost from penetrating through the sides to the roots of the plants. In very hard winters it will be proper to lay peas-haulm or straw over them, which will keep out the frost better than mats, and, lying hollow, will admit the air to the surface of the ground, and also permit the exhalations to pass off, whereby the earth will be kept dry and the roots be prevented from rotting, which is often the consequence of covering the beds too closely. This light covering must be removed in mild weather, and used only in very hard frosts, for where the beds are covered with tan or sea-coal ashes, no common frost can penetrate through: and if these coverings be suffered to remain in mild weather, the flower-stems will be drawn up to a great height, and become very weak; and the footstalks of the flowers will be long and slender, and therefore incapable of supporting the bells, which is a great disadvantage to the flowers, one

of the greatest beauties of which consists in the regular disposition of their bells. When the hoops are fixed over the beds, the rotten tan should be nearly all removed as carefully as possible, that the leaves may not be bruised or injured. It had better be done by hand, as the flower-stem of the hyacinth will be then breaking out of the ground. When the flower-stems have reached their height, before the flowers expand, place a short stick down by each root, to which, with a wire formed into a hoop, the stem of the flower should be fastened, to support them from falling; otherwise, when the bells are fully expanded, their weight will incline them to the ground, especially if they are not screened from the wind and rain. During their season of flowering they should be covered in the heat of the day from the sun and heavy rains, and frosty nights; but the morning and evening sun, with gentle showers, they ought to enjoy. With this management you may continue your hyacinths in beauty at least one whole month, and sometimes more, according to their strength, or the favourableness of the season. When their flowers are quite decayed, and the tops of the leaves begin to change colour, you must carefully raise the roots out of the ground with a narrow spade, or some other handy instrument, which is what Dutch gardeners call *lifting* them. In doing this the instrument must be carefully thrust down by the side of the root, being cautious not to bruise it, as well as to put the implement below the bottom of the root; then, by the forcing of the spade on one side, the fibres of the root are raised, and separated from the ground. This is intended to prevent their receiving any more nourishment from the ground; for by imbibing too much moisture at this season, the roots frequently rot after they are taken up. A fortnight after this operation, the roots should be entirely taken out of the ground, and carried to beds upon which the morning sun only shines, and laid upon a ridge with their leaves out, to drain off the moisture, as before directed. Here they should remain until the green leaves are entirely decayed, which perhaps may be in three weeks' time. The Dutch gardeners term this the ripening of the roots, because it causes them to become firm, smooth in the outer cover, and of a bright purple colour: whereas the roots which are permitted to remain undisturbed till the leaves and stalks are quite decayed, will be large and spongy, with their outer coats of a pale yellow colour; for the stems of many of these flowers are very large, and contain a great quantity of moisture, which, if suffered to return into the roots, would infallibly destroy many of them. After they are ripened, take them out of the ground, and wipe them clean with a soft woollen cloth, taking off all the decayed parts of the leaves and fibres, putting them into open boxes where they may lie singly, and be exposed to the air, but carefully preserved from moisture. They should not be suffered to remain where the sun may shine upon them, and may be thus preserved until September, which is the season for replanting them. You must then separate all the strong-flowering roots, planting them in beds by themselves, that they may make an equal appearance in their flowers. The offsets and smaller roots may be planted in a separate bed for one year to acquire strength, and at the end of a second year will probably be as vigorous as the older roots. The single and semi-double flowers should be planted also in a bed by themselves, where they must be carefully sheltered, as before directed, especially from frost, until the flowers are blown; at which time their covering should be entirely removed, the open air admitted, and the flower-stalk supported with sticks, which, though the weather may soon deface the beauty of their flowers, is yet absolutely necessary to promote their seeding. When the seeds are

quite ripe, cut off the vessels, and preserve them with the seeds therein until the season for sowing it. Observe, however, that after these flowers have produced seeds, they seldom flower so well again, at least not in two years after; so that the best method to obtain good seeds is to plant new roots every year for that purpose. Although these roots are by most persons taken up every year, where the ground has been well prepared, they may remain two years, and will increase more in the second year than the first: but the flowers are certainly more liable to degenerate; therefore those who cultivate them for sale take up their roots annually, when they are large and saleable, but leave the offsets and small roots two years in the ground. There are some persons who suffer their hyacinth roots to remain three or four years unremoved, which causes a much greater increase of roots than when they are annually taken up. But the roots by this great increase are frequently degenerated, so as to produce single flowers. Single hyacinths may be planted a week or two sooner than the double ones, and will bloom two or three weeks earlier. Upon these the cultivator must depend for seed, for the double ones rarely produce any: save your seeds from those plants which have strong straight stems, and a regular well-formed pyramid of flowers which are semi-double. Do not gather it till it is perfectly black, when the pericarp will appear yellow on the outside, and begin to open. Then cut off the stem, and place it in a dry, airy, cool place, till the time of sowing, which may be either the end of October, the beginning of March, or in August; which last Mr. Miller recommends. Some say, that if the bulbs of double hyacinths be planted sooner than the middle of October, they will be apt to come up during the winter, and thus be injured by severe frosts; and if it be deferred later than the middle of November, the bulbs will begin to put out fibres, which will weaken them. Such bulbs as are four or five years old flower strongest in England, and after this gradually decline: but in Holland, the same bulb will produce bloom twelve or thirteen years together, nor is it ever known to die through mere age. Persons who are nice about their flowers, erect a covering over them during the flowering time, to keep off the rain without excluding the light, and to keep off cold winds, which are frequently very injurious at the early season in which these delicate flowers are in bloom. This awning should be of coarse linen, on a frame of wood, made to roll up-easily, that in mild cloudy weather the flowers may have the full benefit of the sun and air: and it should not continue on more than a fortnight or three weeks, for it weakens the bulbs. Florists differ as to the proportion of the materials of the compost in which the bulbs are to be planted. Some, instead of half fresh earth, recommend only one-third, with the same quantity of rough sea or river sand, and the remaining part to be one-fourth old rotten cow-dung and the rest the earth of decayed leaves: some put in tanner's bark, rotten wood, or old saw-dust: others reprobate tan, as retaining an astringency which is pernicious to delicate bulbous flowers. In using fresh earth from a pasture, it is necessary to guard against the wire-worm, by minutely inspecting the heap as it is turned over, and picking out that destructive reptile, which is of a yellow colour and about an inch long. The beds should be in a dry airy part of a garden, with a southern exposure, sheltered from the north and east, six feet distant at least from the fence, and made sloping a little towards the sun. It succeeds best in situations near the sea. In more inland parts, the florist must annually introduce fresh bulbs to supply deficiencies, by keeping a reserve in deep narrow pots, to fill up the vacancies in his beds.

8. *Hyacinthus Corymbosus*. Corollas funnel-form; raceme

erect; scape shorter than the leaves; leaves linear, very narrow, commonly three, shorter than a finger's length; scape terminated by a corymb of purple flowers, cloven half way down; style the length of the corolla.—Observed by Kœnig in pastures near the Cape of Good Hope.

9. *Hyacinthus Romanus*; *Roman Grape Hyacinth*. Corollas bell-shaped, half six-cleft, in racemes; stamina membranaceous; leaves very long, the width of the finger; raceme long, round, with very numerous flowers, which are white, and cut beyond the middle; antheræ blue.—Found in the fields near Rome.

10. *Hyacinthus Muscari*; *Musk Hyacinth*. Corollas ovate, all unequal, with one bracte under the pedicel, and another above it; root large, oval, bulbous, from them arise several leaves eight or nine inches long, and half an inch broad. From amongst them arises the stalk, six inches high, which sustains the flowers: it is naked below, but the upper parts are garnished with small flowers growing in a spike; they have ovate pitcher-shaped petals, which are reflexed at their brim, and are of an ash-coloured purple, or obsolete faded colour, but have an agreeable musky scent, and, when in some quantity, will perfume the air to a considerable distance. It flowers in April, and ripens seed in July. Of this there are several varieties. One with the same coloured but larger flower on the lower part of the spike, while the flowers on the upper part of the spike are yellow, and emit a very grateful odour. Another, with very large yellow flowers, sells for a guinea a root among the Dutch florists. Native of the Levant.—These plants are hardy, will thrive in the open air, and require no other culture but to take up the roots every second or third year to separate the bulbs; for some of them multiply fast, and when the bunches of bulbs become large, they do not flower so strong. They ought to be taken up soon after their stalks and leaves decay, and spread on a mat in a dry shady room for a fortnight, to dry; after which they may be kept in boxes till Michaelmas, when they may be planted in the borders of the flower-garden, and treated in the same way as the common hyacinths. They are all easily increased by offsets, which most of them send out in plenty; so that there is no occasion to sow the seeds, unless it be to gain new varieties.

11. *Hyacinthus Convallarioides*. Corollas bell-shaped, ovate, pendulous; scape filiform; flowers without leaves, yellow.—Found by Thunberg at the Cape of Good Hope.

12. *Hyacinthus Monstrosus*; *Feathered Hyacinth*. Corollas subovate; root large, bulbous, producing several plain leaves, a foot long, and half an inch broad; flower-stalk a foot and half high, naked at the bottom for about seven or eight inches, above which the panicles of flowers begin and terminate the stalks. The flowers stand upon peduncles, which are more than an inch long, each sustaining three, four, or five flowers, the petals of which are cut into slender filament-like hairs: they are of a purplish colour, and having neither stamina nor germen, never produce seeds. It flowers in May; and after the flowers are past, the stalks and leaves decay to the root, and new ones arise in the following spring.—Native of the south of Europe.

13. *Hyacinthus Comosus*; *Purple Grape Hyacinth*. Corollas angular, cylindrical, the upper ones barren, on longer pedicels; bractes small, acuminate; bulb as large as a middling-sized onion; leaves five or six, a foot or eighteen inches long; flower-stalks above a foot high, lower half naked, upper half sustaining a loose raceme of flowers; the lower flowers are farther asunder, are upright before they expand and while they continue, but afterwards stand out horizontally on pedicels half an inch long; their colour is a yellowish green, with blue or purple at the end; these are fertile.

The upper ones are smaller, barren, stand upright, form a corymb, and are blue or violet, as are also their long pedicels. Parkinson remarks, that "the whole stalk with the flowers upon it doth somewhat resemble a long purse-tassel, and thereupon divers gentlewomen have so named it." This species is more distinguished by its singularity than its beauty, and by the difference between the lower and the upper barren flowers. It varies with white and blue flowers, but the purple is most common. They appear with us at the end of April and beginning of May. Mr. Miller received both roots and seeds from Spain and Portugal.—Native of the corn-fields in the south of Europe. Mr. Curtis calls it *Tassel Hyacinth*: this is the name Parkinson alluded to; see above.

14. *Hyacinthus Botryoides*; *Blue Grape Hyacinth*. Corollas globular, uniform; leaves channelled, cylindrical, strict, three lines wide, straight on account of their short petioles; spike with from twenty to thirty flowers; the teeth of the corolla are white, and the uppermost are small. It differs from the next species, in having the leaves upright, the bunch of flowers smaller, the flowers themselves larger, rounder, of a paler and brighter blue. It is now seldom met with but in long-established gardens; wherever once admitted, it is not easily rooted out; and if permitted to scatter its seed, will fill the ground with its roots.—Native of the vineyards and arable fields of France, Italy, and Germany. This and the next species are alike troublesome by their great increase; and this will not flower readily in an open border. It is a good method to plant the bulbs in moderately sized pots, filled with light earth, and to plunge them in the borders to flower: in the autumn they should be taken out, and the offsets thrown away.

15. *Hyacinthus Racemosus*; *Clustered Grape Hyacinth*. Corollas ovate, the upper ones sessile; bracts solitary, very short; leaves loose; bulb small; scape a span high, blue under the flowers, compressed at top, terminated by a close globular spike or raceme, of from forty to fifty dark blue flowers, with a three-cornered mouth: they are imbricated downwards, have very short peduncles, a sweetish smell, somewhat like new starch or plums; hence Mr. Curtis calls it the *Starch Hyacinth*. This is more common in our gardens than the preceding, for which it is often mistaken: it flowers in April and May.—Native of corn-fields in the south of Europe.—For its propagation and culture, see the preceding species.

16. *Hyacinthus Brevifolius*. Corollas six-parted; raceme drooping; leaves shorter than the scape.—Native of the Cape of Good Hope.

17. *Hyacinthus Flexuosus*. Corollas bell-shaped; raceme upright; leaves linear, longer than the scape.—Native of the Cape of Good Hope.

Hydnum; a genus of the class Cryptogamia, order Fungi.—GENERIC CHARACTER. A horizontal fungus, echinated beneath with awl-shaped fibres. *Observe*. These awl-shaped bodies, which Linneus compares to the prickles of a hedge-hog, are soft, solid, conical or cylindrical substances, emitting seeds from every part of their substance. Linneus has six species of this fungus, five with stems, and one stemless. Of these Hudson has three, all having stems. Dr. Withering enumerates five with stems, and six without. Swartz has added three from Jamaica.—They chiefly grow upon decaying wood.

Hydrangea; a genus of the class Decandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-toothed, permanent, small. *Corolla*: petals five, equal, roundish, larger than the calix. *Stamina*: filamenta ten, longer than the corolla, alternately longer and shorter; an-

theræ roundish, twin. *Pistil*: germen roundish, inferior; styles two, short, distant; stigmas blunt, permanent. *Pericarp*: capsule roundish, twin, two-beaked with the double style, angular, with several nerves, crowned with the calix, two-celled, with a transverse partition, opening by a hole between the horns. *Seeds*: numerous, angular, acuminate, very small. ESSENTIAL CHARACTER. Capsule two-celled, two-beaked, containing many seeds. *Corolla*: five-petalled. *Calix*: five-cleft, superior.—The species are,

1. *Hydrangea Arborescens*; *Shrubby Hydrangea*. Leaves ovate, smooth, alternate; stamina longer. This has a spreading woody root, which produces several soft, pithy, woody stems, from three to four feet high; they are four-cornered when young, and have a green bark, but as they grow older they become taper, and have a light brown bark; flowers terminating in a cyme; corolla small, white, having an agreeable odour. They appear towards the end of July, and in August, but seldom perfect their seeds in England.—Native of Virginia and Canada. It is easily increased, by parting the roots at the end of October, which is also the best time to transplant them. It should have a moist soil, for it grows naturally in marshy places, and requires no other culture but to be kept free from weeds, and to have the ground between them dug every winter. If the stalks should be killed by severe frosts, the root will send out new ones in the spring.

2. *Hydrangea Radiata*; *Downy Hydrangea*. Leaves lobed, tomentose underneath. The stem is rather shrubby, branched, and growing to the height of about five feet. The leaves are foot-stalked and stand opposite; the lower surface is downy, and of a silvery appearance.—Found in Carolina and Florida.

3. *Hydrangea Hortensis*; *Garden Hydrangea*, or *Chinese Guilder Rose*. Leaves elliptical, serrate, very smooth; stamina all of an equal length; root fibrous, much branched, whitish; stems several growing together, erect, shrubby, branched, round, with a smooth brown bark; branches opposite, each pair crossing the others, round, smooth, leafy, green, with dark purple spots, flowering at the top; cymes terminating, the size and figure of the Common Guilder Rose, and, like that, almost entirely composed of radiated abortive flowers, of a beautiful rose colour, inodorous, green when young, as well as in decay. Lowreiro informs us, that on dissecting the germen, and viewing it with a microscope, it appeared to be many-seeded, which confirms the idea of its being an *Hydrangea*. It is much valued on account of the profusion of its elegant flowers, which are botanically termed *monstrous*, in the same manner as the *Viburnum Opulus*, or *European Guilder-Rose*. This beautiful plant being very easily increased by cuttings, has been pretty generally diffused within these few years. The soil that it thrives best in, is a good rich loam. Some trials have been made with it abroad, and it is hardy enough, in a sheltered situation and warm soil, to endure most of our winters; but it does not flower so well in the open air as in a green-house: superfluous plants only should, therefore, be ventured in the open borders of the flower-garden.

Hydrastis; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals three, ovate, regular. *Stamina*: filamenta numerous, linear, compressed, a little shorter than the corolla; antheræ compressed, blunt. *Pistil*: germen numerous, ovate, collected into an ovate head; styles very short; stigmas broadish, compressed. *Pericarp*: berry compounded of oblong granulations. *Seeds*: solitary, oblong. ESSENTIAL CHARACTER. *Calix*: none; petals three. *Nectary*: none;

berry composed of one-seeded acini, or granulations.—The only known species is,

1. *Hydrastis Canadensis*; *Canadian Yellow Root*. The root is composed of thick fleshy tubers, of a deep yellow colour within, but covered by a brown skin, sending out fibres from every part in the spring. It sends up one or two stalks, about nine inches high, at their first appearance of a light green, but afterwards changing to a purplish colour, and hairy towards the top. Each stalk has one or two leaves, the lower petioled but the upper embracing; and is terminated by one flower, which is white, and of very short duration, seldom continuing above three or four hours after its expansion. The fruit is red and succulent, a compound berry, like the Raspberry and Mulberry, but not the least resembling the Strawberry in structure. It flowers in May and June, and is a native of Canada. This plant not increasing much, is rather uncommon in the English gardens: it delights in great shade and moisture; and when planted in dry ground, or much exposed to the sun, it rarely lives through one summer. In a moist loamy soil and shady situation, it will flourish, if left three or four years undisturbed.

Hydrocharis; a genus of the class Dicoecia, order Enneandria.—**GENERIC CHARACTER.** *Male.* *Calix*: spathe three-flowered, two-leaved, oblong; perianth proper, three-leaved; leaflets ovate-oblong, concave, membranaceous at the edge. *Corolla*: petals three, roundish, flat, large. *Stamina*: filamenta nine, awl-shaped, upright, in three rows, the middle one puts forth an awl-shaped stipe from the inner base like a style, which is placed in the centre; the two others are connected at the base so that each inner filamentum coheres with each outer; antheræ simple. *Pistil*: the rudiment of a germen in the centre. *Female Calix*: spathe none; flowers solitary; perianth as in the male, superior. *Corolla*: as in the male. *Pistil*: germen roundish, inferior; styles six, the length of the calix, compressed, bifid, channelled; stigmas bifid, acuminate. *Pericarp*: capsule coriaceous, roundish, six-celled. *Seeds*: numerous, very small, roundish. **ESSENTIAL CHARACTER.** *Male*: spathe two-leaved. *Calix*: trifid. *Corolla*: three-petalled. *Filamenta*: the three inner style-bearing. *Female Calix*: trifid. *Corolla*: three-petalled. *Styles*: six. *Capsule*: six-celled, many-seeded, inferior.—The only known species is,

1. *Hydrocharis Morsus Ranae*; *Frog-bit*. Root of many long, thick, white fibres; leaves at each joint of the stalk six or eight together, floating, roundish, kidney-shaped, fleshy, smooth, thick, perfectly entire, almost transparent, reddish underneath, marked with a few circular and many transverse veins: they are about an inch and half in diameter, and when dry, on removing the outer skin, a most beautiful close net-work of veins is seen. Leaf-stalks and flower-stalk each from six to seven inches long; the latter upright, in the male producing three or four flowers, in the female only one; corolla white, with a yellow bottom, a little wrinkled and tender; calix yellow. There is a variety with a double, very sweet-smelling flower, found in abundance by Mr. Ray in a ditch by the side of Aubrey Causeway, close to the great wooden bridge, in the Isle of Ely. Hill and Meyrick inform us that the leaves of these plants are of a very cooling nature, and often externally applied by the country people for swellings and inflammations. This plant increases by runners furnished by pendulous gems, supported on long footstalks. These gems consist of two stipulaceous scales, folded together, within which are curiously enveloped the embryo leaves of the future plant. It flowers from June through the autumn.—Native of most parts of Europe, in deep ditches, and slow streams with a muddy bottom, multiplying itself greatly by

runners, which shoot out to a great length, and at the joints drop down long roots which penetrate deep into the mud.

Hydrocotyle; a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel simple; involucre commonly four-leaved, small; perianth scarcely any. *Corolla*: universal, uniform in figure, not in situation; florets all fertile; proper five-petalled; petals ovate, acute, spreading, entire. *Stamina*: filamenta five, awl-shaped, shorter than the corolla; antheræ very small. *Pistil*: germen upright, compressed, orbiculate, inferior, peltate; styles two, awl-shaped, very short; stigmas simple. *Pericarp*: none; fruit orbiculate, compressed, transversely bipartite. *Seeds*: two, semiorbiculate, compressed. **ESSENTIAL CHARACTER.** *Umbel*: simple, with a four-leaved involucre. *Petals*: entire. *Seeds*: semi-orbiculate, compressed.—The species are,

1. *Hydrocotyle Vulgaris*; *Common Marsh Pennywort*. Leaves peltate, crenate; umbels five-flowered; roots perennial, capillary, whitish; stems creeping, round, smooth, striking root at the joints; leaf-stalks about two inches long; common peduncles single, axillary from the base of the leaf-stalks, which are terminated by two umbels or glomerules, one springing out of the other, each containing from four or five to six and nine florets, which are very small, reddish white, or rose colour, on very short pedicels; seeds of a pale brown colour. The rot in sheep has been vulgarly attributed to this plant, whereas it is pretty certain that neither sheep nor any other quadruped ever eat it. There is a variety of this species called the Italian Floating Hydrocotyle, which has very slender simple fibres, collected into a head issuing from the joints of the stems, and fastening themselves into the mud.—It is a native of Italy. The flowers of these plants being small and hidden by the leaves, are not much remarked, though they are abundant in their season; but the plant is easily known by the petiole of the leaf being inserted into the middle of it, a circumstance uncommon in European plants. Gerard calls it Water Pennywort, Sheep-killing Penny-grass, and Penny-rot; the Germans call it, *Wassernabel*, *Sumpsnabel*; the Dutch, *Waternel*; the French, *Hydrocotyle Commune*, *le Goblet*, *l'Ecnelle d'Eaux*, *l'Herbe des Patagons*; and the Spaniards, *Sombrera d'Agua*. It flowers with us from May or June through July or August, and is a native of the marshes all over Europe, and not unknown even in Jamaica and Japan.

2. *Hydrocotyle Umbellata*. Leaves peltate, crenate-gashed; umbels many-flowered. Linneus describes it as so like the common sort that it has been confounded with it; but it differs in having the scape twice as long as the leaves, and more than twenty florets in a simple umbel.—Native of the marshes of Jamaica.

3. *Hydrocotyle Americana*. Leaves kidney-form, sublobate, crenate. It has the appearance and size of the first species.—Native of North and South America.

4. *Hydrocotyle Hirsuta*. Hirsute: leaves kidney-form, lobate, crenate; whorls four-flowered.—Native of Hispaniola.

5. *Hydrocotyle Asiatica*. Leaves kidney-form, toothletted.—Native of the East Indies, Japan, and the Cape of Good Hope.

6. *Hydrocotyle Chinensis*. Leaves linear; umbels many-flowered.—Native of China.

7. *Hydrocotyle Villosa*. Leaves cordate, entire, villose; root fibrous; peduncles several, filiform, shorter than the leaves, one flowered.—Native of the Cape of Good Hope.

8. *Hydrocotyle Glabra*. Leaves obovate, smooth; stems creeping; flowers axillary, peduncled.—Native of the Cape of Good Hope.

9. *Hydrocotyle Virgata*. Leaves linear, smooth.—Native of the Cape of Good Hope.

10. *Hydrocotyle Linifolia*. Leaves linear-lanceolate, hirsute, entire. It resembles the preceding, but has longer leaves and peduncles. Native of the Cape of Good Hope.

11. *Hydrocotyle Tomentosa*. Leaves obovate, toothed, tomentose; root caulescent, branched on the surface of the earth. The whole plant hoary, tomentose; peduncles lateral next the lower leaves, and of the same length with them; receptacles, the flowers very dark purple; petals white.—Native of the Cape of Good Hope.

12. *Hydrocotyle Tridentata*. Leaves wedge-shaped, trifid, villose.—Native of the Cape.

13. *Hydrocotyle Ranunculoides*. Leaves five-parted, gashed; stem creeping, jointed; umbels simple; petals white.—Native of Mexico, discovered by Mutis.

14. *Hydrocotyle Erecta*. Leaves cordate, crenate; scapes few-flowered, the length of the petioles, having a few flowers at the top.—Native of Jamaica.

15. *Hydrocotyle Moschata*. Leaves kidney-form, seven-lobed, serrate, villose; umbels many-flowered.—Native of New Zealand.

Hydrolea: a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth five-parted; parts oblong, acute, unequal, permanent. *Corolla*: one-petalled, wheel-bell-shaped; tube shorter than the calix; limb five-parted, spreading; segments ovate, incumbent. *Stamina*: filamenta five, awl-shaped, cordate at the base; antheræ oblong, curved, incumbent. *Pistil*: germen ovate; styles two, filiform, spreading; stigmas truncate. *Pericarp*: capsule ovate, two-celled, two-valved; partition contrary. *Seeds*: very many, minute, imbricated, with an ovate large receptacle. *Observe*. In some flowers the calix and corolla are six-cleft, with six stamina. ESSENTIAL CHARACTER. *Calix*: five-leaved; corolla wheel-shaped. *Filamenta*: cordate at the base. *Capsule*: two-celled, two-valved.—The species are,

1. *Hydrolea Spinosa et Quadrivalvis*. Stem with axillary spines; flowers clustered, terminating; spines axillary, spreading.—Native of South America.

2. *Hydrolea Inermis*. Stem unarmed; flowers solitary, lateral, blue; corolla wheel-bell-shaped.—Native of moist places near Canton in China.

3. *Hydrolea Zeylanica*. Stem unarmed; flowers subracemed; leaves lanceolate, alternate, petioled, oval, oblong, quite entire, sharpish, even; peduncles opposite to the leaves, axillary, one-flowered; corolla blue.—Native of the East Indies.

4. *Hydrolea Trigynia*. Stem spiny; leaves oblong, hirsute; flowers three-styled, axillary.—Native of the West Indies.

Hydrophyllax: a genus of the class Tetrandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, upright, four-parted, superior, permanent; segments ovate, acute, margined, somewhat fleshy. *Corolla*: one-petalled, funnel-form; tube longer than the calix; limb angular, four-cleft; segments ovate, revolute; throat bearded. *Stamina*: filamenta four, placed on the tube, decurrent, upright, longer than the corolla; antheræ subhastate. *Pistil*: germen oblong, inferior; style filiform, curved; stigma bifid. *Pericarp*: berry juiceless, ovate, compressed, with three ribs on each side, the middle one higher, with an attenuated margin, a little bowed in, fungous, two-celled, with a transverse partition; seeds solitary, oblong, bowed in a little, three-sided, two-grooved on the inner side, somewhat rugged. ESSENTIAL CHARACTER. *Calix*: four-parted. *Corolla*: funnel-form; fruit ancipital, one-seeded.—The only known species of this genus is,

1. *Hydrophyllax Maritima*. Root simple, filiform, blood-red, long, fleshy, sweet; stem creeping, filiform, smooth, coloured, jointed, sheathed with blunt, membranaceous, permanent sheaths, very long; leaves opposite, spreading, ovate, acute, quite entire, approximating, fleshy, shining; flowers axillary, subsessile, usually two together, but not opposite, erect; corolla pale blue; antheræ blue. It has the appearance of *Arenaria Rubra Maritima*, but is larger—Found in the driving sand upon the sea-shore near Guduluhr in the East Indies.

Hydrophyllum: a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, scarcely shorter than the corolla, spreading, permanent, with awl-shaped segments. *Corolla*: one-petalled, bell-shaped, five-cleft; segments upright, obtuse, emarginate. *Nectary*: a cleft closed by two longitudinal converging plates, fastened to the petal within the middle of each segment. *Stamina*: filamenta five, awl-shaped, longer than the corolla; antheræ incumbent, oblong. *Pistil*: germen superior, ovate, acuminate; style awl-shaped, the length of the stamina; stigma bifid, acute, spreading. *Pericarp*: capsule globular, one-celled, two-valved; seed single, round, large; according to Gærtner, four, resting within a berried receptacle. ESSENTIAL CHARACTER. *Corolla*: bell-shaped, having five longitudinal melliferous streaks on the inside. *Stigma*: bifid. *Capsule*: globular, two-valved.—The plants of this genus endure cold well, but require to be planted in a moist rich soil, and shady situation, and will not thrive in a warm dry soil unless constantly watered in dry weather. They may be increased by parting the roots in autumn, and will require abundant watering, if not well rooted before the spring.—The species are,

1. *Hydrophyllum Virginicum; Virginian Water-leaf*. Leaves pinnatifid; root composed of many strong fleshy fibres, which spread wide on every side. The flowers rise with foot-stalks from the root, having one or two small leaves of the same shape with the lower; they are in loose clusters hanging down, and of a dirty white colour, making no great show; seeds regularly four, but often fewer, nestling in the receptacle, irregularly ovate and angular, elegantly netted, with very minute excavations. It flowers here in May and June, sometimes ripening seed in August.—Native of moist spongy ground in Virginia and Carolina.

2. *Hydrophyllum Canadense; Canadian Water-leaf*. Leaves lobate, angular. It has the same structure as the preceding.—It flowers in May, and is a native of Canada.

3. *Hydrophyllum Appendiculatum*. Plant very rough; radical leaves somewhat winged; bunches of flowers subpaniculate; flowers pale blue, the calix extremely hispid, and almost the length of the corolla.—Found on shady rocks near springs in Virginia; also near Harper's Ferry, Tennessee, North America.

4. *Hydrophyllum Lineare*. Leaves linear; branches elongated.—Mr. Lewis found this plant on the banks of the Missouri.

Hymenæa: a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, coriaceous; tube short, turbinate, compressed, permanent, with an oblique mouth; limb five-parted, almost regular, upright, deciduous; segments ovate, blunt, two, opposite, flattish, a little broader; two others concave, with one side narrower. *Corolla*: five-petalled, inserted into the neck of the calix, somewhat subpapilionaceous; petals almost equal; banner, the two uppermost petals obliquely ovate, obtuse, sessile, at the upper concave segment of the calix; wings two; petals similar, lateral, a little narrower; keel the

lowest petal channelled and excavated, approximating to the wings, within the hollow segment of the calix. *Stamina*: filamenta ten, distinct, awl-shaped, erect, bent down above the middle, very long between the keel and the wings, inserted into the neck of the calix; antheræ linear, fixed by the back. *Pistil*: germen sabre-shaped, compressed, pedicelled; style very long, bristle-shaped, bent down; stigma thickened, obliquely truncate. *Pericarp*: legume woody, very large, ovate-oblong, obtuse, one-celled, filled with farinaceous pulp. *Seeds*: several, four to eight, large, ovate, wrapped up in pollen and fibres. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Petals*: five, almost equal. *Style*: twisted inwards. *Legumes*: filled with farinaceous pulp.—The only known species is,

1. *Hymenæa Courbaril*; *Locust Tree*. Stem large, covered with a russet bark, dividing into many spreading branches, garnished with smooth stiff leaves which stand by pairs, their base joining at the footstalk. The flowers are produced in loose spikes at the end of the branches, some of the short ligneous footstalks supporting two, and others three flowers, which are composed of five yellow petals striped with purple, and are succeeded by thick fleshy brown pods, shaped like those of the garden bean, six inches long, and two and a half broad, of a purplish brown colour, and ligneous consistence, containing seeds inclosed in a whitish substance of fine filamenta as sweet as honey. This substance, which purges when fresh gathered, but loses that property as it grows old, is eaten by the Indians with great avidity. The wild bees are fond of building their nests in this tree, which grows to a considerable size, and is looked upon as excellent timber; but it must be very old before it is cut, otherwise the heart will be but small. It is in great request for wheel-work in the sugar-mills, particularly for cogs to the wheels, being extremely hard and tough, capable of receiving a fine polish, and so heavy that a cubic foot weighs about a hundred pounds. From between the principal roots of the tree a fine yellowish or red transparent resin, called gum-anime, exudes. It is collected in large lumps, and makes a varnish superior to Chinese lacca, when dissolved in the highest rectified spirits of wine. It burns readily, and with a clear flame, emitting a grateful fragrant smell, on which account it is sometimes ordered by way of fumigation, in the chambers of persons labouring with asthmas or suffocating catarrhs. Its vapours not only strengthen the head, but all parts of the body affected with cold. Some apply it outwardly, dissolved in oil or spirits of wine, to strengthen the nerves. An oil may be distilled from it, efficacious in palsies, cramps, and contractions of the sinews. A decoction of the leaves expels flatulencies, and gives ease in colic pains, by gently opening the bowels; and the inward bark is an excellent vermifuge, in substance or decoction.—Native of the West Indian Islands, where it grows in great plenty, and is a very large spreading tree. It is easily raised from fresh seeds, which must be sown in pots, and plunged into a hot-bed of tanner's bark. There should be but one seed put into each pot, or, if there be more, when the plants appear they should be all drawn out to one, soon after they come up, before their roots entangle, when it will be hazardous doing it; and if great care be not taken, the plant intended to be left, may be drawn out with the other. As the roots are but slender, this plant is very difficult to remove, for unless a ball of earth be preserved to their roots, they seldom survive their removal, and on that account they must be seldom transplanted from one pot to another. The plants must constantly remain in the tan-bed on the stove, and should be treated in the same way as other tender plants of the same country, giving them but little water, especially in the winter.

They make considerable progress for two or three months after they first appear, after which they will perhaps stand a whole year without shooting, growing very like the Cashew-nut, or Anacardium, and being very difficult to preserve long in this country.

Hyobanche; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth seven-leaved; leaflets linear, acuminate, erect, the length of the corolla. *Corolla*: one-petalled, ringent; upper lip vaulted, emarginate; lower none. *Stamina*: filamenta four, twin, inserted into the base of the corolla, of a middling length; antheræ ovate, nodding, opening on the upper side. *Pistil*: germen ovate; style filiform, curved at the top; stigma thickened, blunt, emarginate. *Pericarp*: capsule roundish, two-celled. *Seeds*: numerous, small. *Observe.* The calix and corolla prevent it from being associated with *Orobanche*. **ESSENTIAL CHARACTER.** *Calix*: seven-leaved. *Corolla*: ringent, without any lower lip. *Capsule*: two-celled, many-seeded.—The only known species is,

1. *Hyobanche Sanguinea*. Stem half a foot high, quite simple, woody, thick, closely imbricated with leaves, or rather ovate scales, convex on the outside, smooth, blunt; spike terminating, dense, fleshy, villose, the length of the stem, and three times as broad, imbricated with bractes and flowers. The whole plant resembles the *Orobanche* in structure, but is blood-red. Parasitical at the roots of shrubs, at the Cape of Good Hope.

Hyoscyamus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, ventricose at bottom, with a five-cleft sharp mouth, permanent. *Corolla*: one-petalled, funnel-form; tube cylindrical, short; limb from erect spreading, half five-cleft; segments obtuse, one broader than the others. *Stamina*: filamenta five, awl-shaped, inclining; antheræ roundish. *Pistil*: germen roundish. *Style*: filiform, the length of the stamina; stigma headed. *Pericarp*: capsule ovate, obtuse, marked with a line on each side, two-celled, two capsules closely approximating, with a lid opening horizontally; receptacles half ovate, fixed to the partition. *Seeds*: numerous, unequal, irregular. *Observe.* The seventh and eighth species differ in having the fruit seldom opening, and a more regular corolla. **ESSENTIAL CHARACTER.** *Corolla*: funnel-form, obtuse. *Stamina*: inclined. *Capsule*: two-celled, covered with a lid.—This genus consists of biennial plants, which perish soon after they have perfected their seeds. They flower in June and July, and their seeds ripe in the autumn, which, if permitted to scatter, will produce plenty of the plants in the following spring; or if the seeds be sown at that season, they will succeed much better than plants sown in the spring, which seldom come up in the same year. They are all hardy except the second species, and require no other culture than weeding, and thinning where they grow too close.—The species are,

1. *Hyoscyamus Niger*; *Black or Common Henbane*. Leaves stem-clasping, sinuate; flowers sessile. It has long fleshy roots, which strike deep into the ground, and are branched; bottom leaves soft, deeply gashed on their edges, and spreading on the ground. The stalks, which do not rise till the second spring, have leaves of the same shape, but smaller and clasping, and about two feet high: on the upper part are flowers standing on one side in a double row, sitting close to the stalk alternately. The corolla is yellow, or rather pale yellowish brown, beautifully netted with purple veins, and a dark purple eye or base; seeds very abundant, gray, excavated and angular. The whole plant is covered with unctuous fetid hairs, producing a strong and peculiar odour, greatly

affecting the head of some persons as soon as they come within its atmosphere. Linneus says, that it is not touched by any animal except the goat, who is not partial to it. He informs us that the roots of it scattered about a house will drive away mice; but who would endanger the lives of children and ignorant persons by strewing their apartments with so dangerous a root, which the illustrious Swede himself acknowledges to have been frequently eaten for parsneps, producing delirium, madness, convulsions, and death. The root, herb, and seeds, taken internally, are deservedly reputed poisonous, for well-attested instances of their bad effects are recorded. Notwithstanding this, however, henbane has been used as a medicine from time immemorial, and there is no doubt of its being a useful medicine under proper management. The Edinburgh college orders the expressed juice of the plant to be evaporated to an extract, in which state it may perhaps be advantageously joined with opium, where the purgative effects of that medicine are desirable, and costiveness is to be avoided: the dose is from half a scruple to half a drachm. Villars says, the extract may be safely given in a dose of two or three grains, gradually increasing the quantity; for it has neither odour nor activity, if the plant be young, or if the extract be made with an open strong fire. He administered it internally in epilepsy and convulsions, and found that it put off the fits, and diminished their violence, though it did not effect a cure. Baron Stoerek and others have not only recommended it in the above disorders, but in mania, hæmoptoe or spitting of blood, and the dry cough, and universally wherever an anodyne is wanting to quiet the nervous irritations; beginning with a single grain of the extract, and gradually increasing the dose to five grains. Some more daring practitioners proceed as far as fifteen grains; but in general it is more advisable to continue the use of the medicine longer, than to give it in very large doses. It has been administered, even in a cataract, to the quantity of two grains, mixed with Mercurius Dulcis. The leaves, bruised and fried, have been successfully applied to the piles and muscular spasms. Like other narcotics, they assist in softening indurations of the glands. An oil expressed from the seeds is used outwardly as an anodyne; and the common people sometimes smoke them for the tooth-ache, or put a piece of the root boiled in milk at the root of the tooth. The roots also cut in pieces, and strung like beads, are used for anodyne laces to hang about children's necks, for preventing fits, and causing the teeth to breed easily; and many wonders are said to have been wrought by this imaginary preventive. A decoction of the henbane has been given in clysters, to assuage pains of the intestines; but this is dangerous: and, indeed, taken altogether, henbane is a medicine not to be trifled with, nor to be at all taken without good advice. Mr. Miller warns us, that a mixture of these roots having been imported with Gentian, were productive of very bad effects.—A variety of this species, has the corolla and antheræ of a pure brimstone colour, without the least tinge of purple. The seeds being sown in the botanic gardens at Chelsea, produced the very same variety.—Henbane is a biennial plant, flowering in June, and native of waste places, particularly near towns and villages in most parts of Europe. It probably obtained its English name from a notion that it is injurious to poultry, which, whether true or not, we have had no opportunity of ascertaining. The Germans call it, *Bilsenkraut*; the Dutch, *Bilsenkruid*; the Danes, *Bulme*, *Honsebane*, &c.; the Swedes, *Bolmort*, *Honsabate*; the French, *La Jusquiame*; the Italians, *Giusquiamo*, *Fava-porcina*; the Spaniards, *Beleno*, *Veleno*; the Portuguese, *Miendro*, *Velenho*, *Yosciamo*; and the Russians, *Belena*.

2. *Hyoscyamus Reticulatus*; *Egyptian Henbane*. Stem-leaves petioled, cordate, sinuate, acute; floral-leaves quite entire; corollas ventricose; branching stalk two feet high; the whole plant is smooth; flowers on a very short peduncle; corolla bell-shaped, red, beautifully netted with dark veins. Annual, flowering in July.—Native of Egypt, Syria near Aleppo, and of the island of Candia. This plant requires a warm situation and a dry soil, in which it will endure the winter better than in rich ground.

3. *Hyoscyamus Albus*; *White Henbane*. Leaves petioled, sinuate, obtuse; flowers sessile. This resembles the Black in most circumstances, but the leaves are more rounded and obtuse, very soft, bearded with white hairs, as is the stem; flowers fewer, the lower on longer peduncles, the upper on very short ones. The corolla varies with the base dark purple or green. Annual, flowering in August, and a native of the south of Europe. The seeds, which are very numerous, small, compressed a little, incurved or kidney-form, closely scrobiculate and whitish ash-coloured, are recommended as cooling, emollient, and excellent to ease pain. They procure sleep like opium, but without affecting the head. Taken in doses of half a scruple, they assuage the pain arising from colic, and are excellent in coughs and other disorders of the breast, spitting of blood, immoderate menstrual discharges, and all other hæmorrhages.

4. *Hyoscyamus Aureus*; *Golden-flowered or Shrubby Henbane*. Leaves petioled, toothed, acute; flowers peduncled; fruits pendulous. This is a perennial plant, with weak stalks requiring support. The flowers come out at each joint of the stalk, they are large, and of a bright yellow, with a dark purple bottom. The style is much longer than the corolla. Prosper Alpinus, and others, make two varieties of this, differing only in size, and the shade of colour in the corolla. It flowers most part of the summer, and sometimes ripens seed in autumn.—Native of Candia, and other parts of the Levant. The seeds, sown in pots as soon as they are ripe, and placed under a hot-bed frame in winter, will produce plants in the spring, but rarely succeed if put in the ground at that season. This species will last several years in pots, if screened from the frosts in winter, when it must be placed under a common hot-bed, where it may enjoy as much free air as possible, and will thrive better there than if more tenderly treated. It may be easily propagated by cuttings, which, if planted in a shady border during any of the summer months, will take root in a month or six weeks, and may be removed into pots, and treated like the old plants.

5. *Hyoscyamus Muticus*. Leaves petioled, ovate, acute-angular; calices awnless; bractes undivided; stem a foot high, a finger thick, erect; corolla on the outside at first green, then whitish, on the inside very dark purple, with the two lowest segments whitish, but finally the whole corolla becomes white and unspotted. Biennial.—Native of Egypt and Arabia.

6. *Hyoscyamus Pusillus*; *Dwarf Henbane*. Leaves lanceolate, toothed; lower floral leaves in pairs; calices spiny; stem a hand high, brittle, oblique, undivided, having long hairs; corolla yellow, with a dark throat. Biennial, flowering in July.—Native of Persia.

7. *Hyoscyamus Physaloides*; *Purple-flowered Henbane*. Leaves ovate, quite entire; calices inflated, subglobular; root perennial; stems a foot high, simple, erect, round, rough-haired; corollas purplish, funnel-form, upright.—Native of Siberia.

8. *Hyoscyamus Scopolia*; *Nightshade-leaved Henbane*. Leaves ovate, entire; calices inflated, bell-shaped, even; root perennial, transverse, knobbed, thick, irregular, branched,

flexuose, thickness of the human thumb; stem herbaceous, annual, round, smooth; peduncles one-flowered, pendulous from the axils, weak, two inches long; corolla of the same shape and colour as in *Atropa Belladonna*; seeds kidney-form, rather large, elegantly dotted very closely in rows, with little holes, and of a very pale yellow colour. It flowers with us in May, and in April in the woods of Friuli in Idria, of which it is a native.

Hyoseris; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER. *Calix*: common cylindric, angular, consisting of about eight leaves, permanent; scales lanceolate, erect, acute, slightly keeled, equal, calicled at the base, with fewer, very short, close scales. *Corolla*: compound, subimbricate, uniform, composed of many hermaphrodite corollets; proper one-petalled, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: germen oblong; style filiform, the length of the stamina; stigmas two, reflex. *Pericarp*: none; the common calix close or spreading. *Seeds*: solitary, oblong, membranaceous, streaked on one side along the middle, almost the length of the calix. ESSENTIAL CHARACTER. *Calix*: almost equal; down hairy and calicled; receptacle naked.—All the plants belonging to this genus, except the sixth, are hardy, and may easily be propagated from seeds either sown in the spring, or left to scatter of themselves. They require in general a dry soil.—The species are,

* *Stem naked.*

1. *Hyoseris Fœtida*; *Stinking Hyoseris*. Scapes one-flowered; leaves pinnatifid; seeds naked; root perennial, single, cylindrical, thick, woody, fetid; flower middle-sized, yellow above, and red beneath. The whole plant has a disagreeable smell, and much resembles Dandelion, but the flower is smaller, and of a deeper yellow colour. They appear in July.—Native of the mountains of Italy, Dauphiny, Carniola, and Switzerland, and found in various parts of Germany and France.

2. *Hyoseris Radiata*; *Starry Hyoseris*. Scapes one-flowered; leaves smooth, runcinated, with toothed angles, laciniated at top; the peduncles and rachis of the leaves farinaceous.—Native of the south of France; the county of Nice, on hills near the coast; and of Spain.

3. *Hyoseris Lucida*; *Shining Hyoseris*. Scapes one-flowered; leaves somewhat fleshy, runcinate, angular, toothed. This very much resembles the preceding. Marginal seeds scarcely downy. It flowers from June to August.—Native of the Levant.

4. *Hyoseris Scabra*; *Rugged Hyoseris*. Scapes one-flowered; leaves rugged; seeds downy. Annual.—Native of Sicily, of the county of Nice, and neighbourhood of Villa Franca.

5. *Hyoseris Virginica*; *Virginian Hyoseris*. Scapes one-flowered; leaves lanceolate, lyrate, smooth; corolla deep yellow; seeds four-cornered.—Native of Virginia.

6. *Hyoseris Pygmæa*; *Dwarf Hyoseris*. Scapes one-flowered; leaves spatulate, toothed, ciliate; calices hairy; hairs and cilia forked; down stiped, feathered. This is an annual plant, flowering in June and July, and a native of Madeira. It can only be raised in a green-house.

7. *Hyoseris Minima*; *Least Hyoseris*. Stem divided, naked; peduncles thickened; root annual, small but woody, with a few rigid fibres; corolla yellow; seeds oval, striated. Dr. Withering calls this plant Small Swine's-eye. It flowers in May and June, and is a native of most parts of Europe, in pastures and corn-fields of a sandy soil. Though not very common in England, it is found about Hampton Court, and

in Teddington field; near Waltham Stow, in Essex; Perth-shore, in Worcestershire; in the neighbourhood of Norwich; near Gamlingay, in Cambridgeshire; Spratton, in Northamptonshire; and about Forfar, and between Dudee and St. Andrews, in Scotland.

* *Stem leafy.*

8. *Hyoseris Hedynnois*; *Branching Hyoseris*. Fruits ovate, smooth; stem branched, weak, and bending at each joint; flower yellow, small, nodding. Those of the ray have only a rim. It flowers in June.—Native of the south of Europe.

9. *Hyoseris Rhagadioloides*; *Nipplewort Hyoseris*. Fruits ovate, hairy; stem branched. It is an annual plant, flowering in July and August, and native of the south of Europe.

10. *Hyoseris Cretica*; *Cretan Hyoseris*. Fruits ovate, rugged; stem branched; root annual, round, fibrous, white within, brown without; flowers solitary, erect, terminating, and axillary; corollets short, pale yellow. It flowers in May and June, with us in June and July.—Native of Candia, of the county of Nice, and common about Madrid.

11. *Hyoseris Montana*. Plant very glabrous, procumbent; leaves lanceolate, very entire; scape one-flowered.—Found by Michaux on the mountains of Carolina.

12. *Hyoseris Angustifolia*. Leaves linear, lanceolate; scape one-flowered; flowers large, bright yellow.—Found in pastures and fields in Virginia and Carolina.

13. *Hyoseris Caroliniana*. Leaves lyrate at the base; scape one-flowered.—Native of Carolina.

Hypocoum; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth two-leaved, small; leaflets ovate, acute, erect, opposite, deciduous. *Corolla*: four-petalled, the two outer petals opposite, broader, trifid, obtuse, the two inner alternate with the others, semitrifid; the middle segment concave, compressed, erect. *Stamina*: filamenta four, awl-shaped, erect, covered by the middle segment of the inner petals; antheræ erect, oblong. *Pistil*: germen oblong, cylindrical; styles two, very short; stigmas acute. *Pericarp*: silique long, curved inwards, jointed. *Seed*: solitary in each joint of the pericarp, globular, compressed. *Observe*. The stamina of the third species seem to be tetradynamous. ESSENTIAL CHARACTER. *Calix*: two-leaved. *Petals*: four, the two outer broader and trifid; fruit a silique.—The plants of this genus being all annual, are propagated by seeds, which should be sown soon after they are ripe, on a bed of light fresh earth, where they are to remain, for they seldom succeed if transplanted. When the plants come up, clear them from weeds, and thin them to the distance of six or eight inches. When the seeds are sown in the spring, and the season proves dry, they will not grow the first year, but if the ground be kept clean from weeds, and not otherwise disturbed, the plants will come up in the following spring. The seeds will sometimes lie even till the third spring. Hence it is best to sow them in a warm border in autumn, which will produce stronger plants, and be more likely to perfect seeds than those sown in spring. The seeds should be divested of their fungous covering before they are sown, for that adheres so close that it prevents their growing until it be decayed. If the seeds are allowed to scatter, they will frequently come up of themselves without any care. In large gardens these plants, which require little room when intermixed with other small annuals, will make a pretty appearance in the borders.—The species are,

1. *Hypocoum Procumbens*; *Procumbent Hypocoum*. Siliques bowed, compressed, jointed; root simple, sometimes bifid, long but annual, having only a few fibres; leaves divided by many incisures resembling those of Fumitory; stems several, slender, somewhat compressed; peduncles each sus-

taining one small yellow flower, appearing in June and July, producing seed in August.—Native of the south of Europe.

* 2. *Hypericum Pendulum*; *Pendulous Hypericum*. Stalks slender. This flowers and seeds at the same time as the first species.—Native of the south of France.

3. *Hypericum Erectum*; *Upright Hypericum*. Siliques erect, round, torulose. The juice of this and of the other species is of a yellow colour, resembling that of Celandine, and is said to operate like opium.—Native of Dauria and Istria.

Hypelate; a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** *Hermaphrodite Flowers.* *Calix*: perianth five-leaved, seldom four-leaved; leaflets ovate, concave, spreading, deciduous, two less than the others. *Corolla*: petals five, ovate, a little less than the calix, deciduous, with a nectariferous umbilicus about the germen. *Stamina*: filamenta eight, spreading round the base of the germen, the length of the corolla; antheræ ovate, cordate. *Pistil*: germen globular, superior; style short, upright; stigma bent down, three-sided, three-grooved, acute. *Pericarp*: drupe pulpy, roundish. *Seed*: nut oval, very smooth, with a single kernel. *Male Flowers* on the same tree, but upon a distinct panicle; calix and corolla as in the hermaphrodite; nectary also as in that; from the middle of this, the *Stamina*: filamenta eight, converging at the base, from erect reflex, and ascending, broader at the base; antheræ ovate, cordate. *Pistil*: three-cornered, rudiment of a germen; style awl-shaped, very small. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled; stigma bent down, three-cornered; drupe one-seeded.—The only known species is,

1. *Hypelate Trifoliata*. This shrubby tree has several trunks, each as big as a man's leg, straight, eight or nine feet high, covered with a smooth cinnamon-coloured bark. Brown observes, that it is full of slender branches, and furnished with many leaves, of the same texture and grain as those of *Lignum Vitæ*, yet remarkably different in form and disposition.—Native of the low lands of Jamaica.

Hypericum; a genus of the class Polyadelphia, order Polyandria.—**GENERIC CHARACTER.** *Calix*: perianth five-parted; segments subovate, concave, permanent. *Corolla*: petals five, oblong, ovate, obtuse, spreading, wheel-shaped, according to the sun's apparent motion. *Stamina*: filamenta numerous, capillary, united at the base in five or three bodies; antheræ small. *Pistils*: germen roundish; styles three, sometimes one, two, or five, simple, distant, the length of the stamina; stigmas simple. *Pericarp*: capsule roundish, with the same number of cells as there are styles. *Seeds*: very many, oblong. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Petals*: five. *Filamenta*: many, connected at the base in five bundles.—This extensive genus consists of herbs, shrubs, or under-shrubs, with cylindrical, ancipital, or quadrangular stems; leaves frequently with pellucid dots; flowers sometimes in cymes, but more frequently in corymbs, with the peduncles often trichotomous and three-flowered, terminating or axillary also; corolla yellow. Linneus divides this genus into four subordinate parts from the number of styles. The predominating number however is three. Jussieu remarks, that it admits of being split into six genera: 1 With five styles, No. 1 to 12; and a capsule with five cells. —2. With three styles, and a three-celled capsule, with the pencils of filamenta scarcely united at the base, as No. 14, &c.—3. With a soft pericarp resembling a berry, almost one-celled, turgid, with a blood-red juice, No. 13, &c. This division has three styles, and in other respects resembles that immediately preceding.—4. With three styles, and a pericarp of three cells, No. 48, &c. the filamenta united up to the middle, the disk of the germen glandular, as are also the

claws of the petals.—5. With two styles and a two-celled pericarp, No. 54, 55, &c.—and, 6. With one style, No. 56, 57, &c. or five styles so closely joined as to seem one.—Whatever may be thought of these distinctions for dividing this natural genus, they will be of considerable use in distinguishing the numerous species.—The species are,

* *With five Styles.*

1. *Hypericum Balearicum*; *Warted St. John's Wort*. Stem shrubby; leaves and branches warted. It rises with a slender, quadrangular, shrubby stalk about two feet high, but in its native soil attains the height of seven or eight feet, sending out several weak branches of a reddish colour, and marked with scars where their leaves have fallen off. Flowers terminating, large, bright yellow; capsules pyramidal, having a strong smell of turpentine, and filled with small brown seeds. It has a succession of flowers during great part of the year, and is therefore valuable. This plant requires no artificial heat. If placed in a dry airy glass-case in winter, where protected from frost, it will thrive better than in a warmer situation. Damp air, however, must be avoided, for the shoots would soon grow mouldy. They should be sparingly watered in winter, but three times a week in summer, when they may also be exposed to the open air. They are propagated by cuttings planted in June, in pots filled with light earth, and plunged into a very moderate hot-bed, shading them from the sun, and refreshing them with water. They will put out roots in six or seven weeks, when they should be carefully taken up, and each planted in a separate small pot, placing them in the shade till they have taken new root; then they should be removed to a sheltered situation, where they may remain till frost comes, when they must be put into a green-house or glass-case. It may also be increased by seeds in autumn.

2. *Hypericum Kalmianum*; *Virginian St. John's Wort*. Stem shrubby; leaves linear, lanceolate; at the end of each branch is produced one pretty large flower, with a blunt calix; stamina as long as the petals.—Native of North America. This, with the other North American sorts, seldom producing any seeds here, may be increased by parting the roots in autumn. It should have a light soil, and an open situation.

3. *Hypericum Cayanense*; *Cayenne St. John's Wort*. Corollas bearded; calices striated; leaves ovate; stem shrubby. This is an upright branching tree, eighteen feet high; racemes compound, terminating; petals white, hirsute within; fruit a berry, with a fulvous staining juice; seeds numerous.—Native of Cayenne.

4. *Hypericum Bacciferum*; *Berry-bearing St. John's Wort*. Corollas bearded; calices even; leaves ovate; stem shrubby, three fathoms high; flowers terminating, paniced, on short peduncles.—Native of Mexico and Brazil. It is a hardy plant.

5. *Hypericum Calicinum*; *Great-flowered St. John's Wort*, or *Tutsan*. Flowers solitary; stem suffruticose, branched; calices obovate, very blunt; leaves distich, oblong. The flowers of the large flowering *Tutsan* are slender, and incline downwards; flowers terminating, peduncled, solitary, bright yellow; the stems are only tinged with red in some places; the leaves on the young shoots are of a beautiful light green, of regular ovate form, and half embrace the stem. It is very hardy, and increases much by the creeping roots. Like the *Periwinkle*, it is a plant well adapted to cover a bank, or bare spots under trees, where few other plants will thrive.—Native of the country near Constantinople. To propagate it, part the roots in October.

6. *Hypericum Pyramidatum*; *Pyramidal St. John's Wort*. Flowers subpaniced; stem slightly four-cornered, herbaceous, branched; calices ovate, acute. It flowers in July and August.—Native country unknown.

7. *Hypericum Alterniflorum*; *Alternate-leaved St. John's Wort*. Flowers axillary, solitary; leaves lanceolate, alternate; stem shrubby; peduncles one-flowered, an inch in length.—Native of the East Indies.

8. *Hypericum Syriacum*; *Syrian St. John's Wort*. Calices leafy; stem herbaceous; leaves alternate, ovate, acute; flowers panicle on the branches, terminating; petals ovate, concave, coriaceous.—Native of dry places in the Syrian desert.

9. *Hypericum Guineense*; *Guinea St. John's Wort*. Flowers subumbelled; stem shrubby; branches round; leaves ovate, acute; bark ash-coloured.—Native of Guinea.

10. *Hypericum Petiolatum*. Stem arboreous; leaves ovate; panicle terminating, brachiate, the length of the leaf; petals obovate, straighter on one side, the length of the calix. It has the appearance of Bay, and abounds with a saffron-coloured juice.—Native of New Granada.

11. *Hypericum Patulum*. Flowers solitary, terminating; stem frutescent, lax; leaves ovate, rolled back at the edge; branches round, purplish, flexuose, ascending, spreading, weak, smooth; corolla yellow, but reddish underneath.—Native of Japan.

12. *Hypericum Ascyron*. Stem four-cornered, herbaceous, erect, simple; leaves even, quite entire; flowers terminating; calix green; corolla pale yellow; petals an inch long.—Found upon the Pyrenees; also in Siberia and Canada. Linneus says the leaves are acute.

**** With three Styles.**

13. *Hypericum Androsæmum*; *Common Tutsan*. Fruits berried; stem shrubby, ancipital; leaves opposite, sessile, ovate, entire, smooth, dark green, glaucous on the under side, netted with numerous projecting veins and nerves, which become ferruginous through age; flowers small for the size of the plant, disposed in a cyme; peduncles round, smooth, usually two or three-flowered, but sometimes one-flowered. The leaves, says Hill, are an excellent cure for fresh wounds: scarcely any thing is equal to them. Those that are young and tender, at the tops of the branches, should be chosen. They are to be bound upon the wound, and will soon stop the bleeding. Many other plants are celebrated for this virtue, but the effects of this are so very singular and efficacious, that no other can be compared with it for healing fresh wounds. From this the French call it *La Toute Saine*; and the English, *Tutsan*: it is also called *Park-leaves*, from being frequently found in parks. The Italians, Spaniards, and Portuguese, call it *Androsæmo*; the Germans, *Konradskraut*, or *Standenartige Johanniskraut*; and the Dutch, *Grootbladig Hypericum*, or *Mansbloed*. It flowers from July to September.—Native of woods and moist hedges in the southern parts of Europe and Britain: it is sometimes found about Hampstead and Highgate; on Bacher-heath and Harefield, Middlesex; in the Oak-of-Honour-wood, near Peckham Rye, and in several parts of Norwood. In many parts of England it is more common; as, in the Duke of Bridgewater's woods at Askeridge, and near Berkhamstead, Herefordshire; in lanes at the foot of Malvern Hill, Worcestershire; and between Worcester and Tewkesbury; in Shot-over plantations; Stokenchurch and Nettlebed woods, Oxfordshire; near Pengwarry in Cornwall; in rocky woods in Westmoreland; at King's Cliff in Northamptonshire; and in Scotland in the woods at Inverary; and at Loch Ransa in the isle of Arran. It is not often admitted into gardens, but is frequently seen in plantations among other shrubs, where it is as ornamental as many others. It may be increased by parting the roots, and loves shade, with a strong soil. The juice expressed from the leaves is claret-coloured.

14. *Hypericum Olympicum*; *Olympian St. John's Wort*. Calices acute; stamina shorter than the corolla; stem shrubby; leaves small, lanceolate, sessile, opposite; flowers terminating, three or four together; petals oblong, bright yellow.—Native of the Levant. It is propagated by parting the roots in September, because the seeds seldom ripen in this country. It will live in the open air, in a warm situation and dry soil: but it will be proper to keep a plant or two in pots, to be sheltered under a frame in winter, to protect them from severe frost. If this be increased by seeds, they should be sown soon after they are ripe, in pots filled with light earth, and placed under a frame in winter; in spring the plants will appear, and when they are fit to remove, may be planted in a warm border, or in pots, and treated as the old plants.

15. *Hypericum Foliosum*; *Shining St. John's Wort*. Stamina the length of the petals; calices lanceolate, acute; leaves oval, oblong, sessile, smooth: it flowers in August.—Native of the Azores.

16. *Hypericum Floribundum*; *Many-flowered St. John's Wort*. Calices ovate, acute, subciliate; stamina shorter than the corolla; leaves lanceolate, elliptic, stem shrubby. It flowers in August, and is a native of Madeira.

17. *Hypericum Arborescens*; *Tree St. John's Wort*. Corollas and calices even, smooth; leaves elliptic; racemes brachiate; stem arborescent; branches quadrangular at the top, smooth, with a purplish bark; peduncles compressed.—Native of the East Indies.

18. *Hypericum Gramineum*; *Grass-leaved St. John's Wort*. Stem herbaceous, four-cornered, dichotomous; leaves oblong parabolic, or ovate-lanceolate; peduncles terminating, and at the divisions filiform, solitary, one-flowered, an inch long; stamina as long as the corolla.—Native of New Caledonia, in the South Seas.

19. *Hypericum Chinense*; *Chinese St. John's Wort*. Peduncles axillary, two-flowered; leaves ovate-lanceolate, quite entire. This is a small tree or shrub, with alternate branches; styles broadish; germen three-cornered.—Imported from China.

20. *Hypericum Cochinchinense*; *Cochin-chinese St. John's Wort*. Peduncles axillary, five-flowered or thereabouts; leaves subpetioled, very close together; stem arboreous. This is a middle-sized tree, about sixteen feet high, with ascending branches, divided into many dusky red branchlets; petals scarlet, ovate, oblong, entire, spreading. The wood of this tree is red, heavy, hard, and tough, and is used for making oars and yards of vessels. The juice of the flowers dyes of a golden colour.—Native of the woods of Cochin-china.

21. *Hypericum Petiolatum*. Leaves ovate; petioled, quite entire, tomentose underneath; stem shrubby, four-cornered, compressed; stipules none; corymb brachiate; sets of stamina oblong, very handsome. This and the tenth species are inadvertently named alike.—Native of Brazil.

22. *Hypericum Canariense*; *Canary St. John's Wort*. Calices blunt; stamina shorter than the corolla; stem shrubby, six or seven feet high, dividing into branches at top; leaves oblong, set by pairs close to the branches, with a strong odour, but less powerful than that of the twenty-fourth species; the flowers of which, those of this plant very much resemble. It flowers from July to September, and is a native of the Canary Islands. This, with the two following species, are propagated by suckers taken off in March, just before they begin to shoot, and planted in a light dry soil; or by cuttings, planted at the same season; or by seeds, sown in August or September, as soon as they are ripe: but as they multiply fast by suckers, the other methods are seldom used.

23. *Hypericum Elatum*; *Tall St. John's Wort*. Calices lanceolate, ovate, acute; stamina longer than the corolla; leaves ovate, oblong; stem shrubby: it flowers in July and August.—Native of North America. See the preceding species.

24. *Hypericum Hircinum*; *Stinking Shrubby St. John's Wort*. Stamina longer than the corolla; stem shrubby, ancipital; flowers in terminating bunches; petals oval. It flowers from July to September.—Native of the South of Europe. See the twenty-second species.

25. *Hypericum Egyptiacum*; *Egyptian St. John's Wort*. Nectaries of the petals lanceolate; stems suffruticose, compressed; leaves like those of Knot-grass, ovate, very small, acuminate, veinless, sessile, longer than the joints of the branches; flowers commonly in pairs, on the branchlets.—Native of Egypt.

26. *Hypericum Orientale*; *Oriental St. John's Wort*. Stipules reflex; leaves oblong, toothletted, crenate; roots in old plants hard, woody, and more than half a foot in length, in young plants a tuft of yellowish fibres three or four inches long; stems from six inches to a foot in height, some upright, others ascending, pale green, a line in thickness, with a small wing descending from one leaf to another: the whole plant has a resinous smell. It varies much in size, as does also the flower, the petals being sometimes ten lines in length. The leaves are bitter, and a little viscid.—Native of the Levant.

27. *Hypericum Scabrum*; *Rugged St. John's Wort*. Stem round, suffruticose, muricated; leaves oblong; flowers small, in terminating corymbs.—Native of Arabia and Barbary.

28. *Hypericum Repens*; *Creeping St. John's Wort*. Stem round, creeping; leaves lanceolate, linear, obtuse; root perennial; flowers terminating, three, the middle one sessile.—Native of the Levant and of Palestine.

29. *Hypericum Prolificum*; *Proliferous St. John's Wort*. Primordial flowers sessile; stem ancipital, shrubby; leaves lanceolate, linear; stamina not longer than the petals. It flowers from June to August.—Native of North America.

30. *Hypericum Ericoides*; *Heath-leaved St. John's Wort*. Leaves linear, imbricated.—Native of Spain and Portugal.

31. *Hypericum Canadense*; *Canadian St. John's Wort*. Leaves linear, lanceolate; stem herbaceous, quadrangular; pericarpia coloured, twice as long as the calix. This has the appearance of Lesser Centaury. Panicle dichotomous, with pedicelled flowers, which are very small, the size of those of Spurge. It flowers from July to September.—Native of North America, and of Canada.

32. *Hypericum Virginicum*; *Virginian St. John's Wort*. Flowers nine-stamined; stem round; leaves ovate, embracing.—Native of North America.

33. *Hypericum Mexicanum*; *Mexican St. John's Wort*. Branches simple; leaves imbricate, ovate; stems a foot high; petals linear.—Native of New Granada.

34. *Hypericum Lævigatum*; *Smooth St. John's Wort*. Leaves ovate, somewhat stem-clasping; calicine leaflets ovate, acute; panicle trichotomous; middle-flower sessile. It flowers in July, and is a native of North America.

35. *Hypericum Reflexum*; *Reflex-leaved St. John's Wort*. Leaves sessile, lanceolate, approximating, reflex; branches tomentose, paniced, terminating. This is a large shrub, with divaricating branches.—Native of the island of Teneriffe.

36. *Hypericum Quadrangulum*; *Square-stalked St. John's Wort*, or *St. Peter's Wort*. Leaves ovate, with pellucid dots; stem quadrangular, herbaceous. It is sufficiently distinguished from all the other species by its square stalk.

61.

Root perennial, somewhat creeping and fibrous; flowers small, terminating in close panicles; branchlets deep red, or blood-colour; peduncles very short; bractes subulate, in pairs; petals finely grooved, concave, marked with lines and dots, filled with a purple liquor, which stains paper with a muddy purple permanent stain. It flowers in July.—Native of most parts of Europe, in moist hedges, shady places, wet meadows, by rivulets, and in bogs. This, with the thirty-seventh, eighth, and ninth; the forty-second, fifth, and ninth; being wild plants, are seldom cultivated in gardens: they are not, however, without their beauty, and may be increased by parting their roots, and permitting their seeds to scatter.

37. *Hypericum Perforatum*; *Common or Perforated St. John's Wort*. Stem ancipital; leaves blunt, with pellucid dots; root perennial, woody, brown. The whole plant is sprinkled over with small black glands, and is quite free from hairs; peduncles from the axils of the upper leaves, two-edged, supporting many flowers in a bushy panicle.—The common people of France, Germany, and Portugal, gather it with great ceremony on *St. John's day*, and hang it in their windows, as a charm against storms, thunder, and evil spirits, mistaking the meaning of some medical writers, who have fancifully given this plant the name of *Fuga Dæmonum*, from a supposition of its efficacy in maniacal and hypochondriacal disorders. In Scotland also it is carried about as a charm against witchcraft and enchantment; and they fancy it cures ropy milk, which they suppose to be under some malignant influence, by milking afresh upon the herb. Horses and swine reject this plant; cows, goats, and sheep eat it. Although *St. John's Wort* is not much regarded in the present practice, yet its sensible qualities, and the repeated testimonies of its virtues, entitle it, as Dr. Cullen observes, to farther trials. To the taste it is astringent and bitter, and its effects seem chiefly to be diuretic. From possessing properties which have been generally called balsamic, it has been used as a vulnerary in external wounds and internal hæmorrhages; for the former purpose the tops and flowers of the plant are infused in oil, and for the latter, an infusion of the plant is made in the manner of tea. It has likewise been given in ulcerations of the kidneys, and has been supposed to possess virtues as a febrifuge. The leaves given in substance are said to destroy worms. The semitransparent dots on the leaves are the receptacles of an essential oil. The flowers tinge spirits and oils of a fine purple colour, which is probably derived from the little glands upon the antheræ and edges of the petals. The dried plant boiled with alum dyes wool of a yellow colour. Hill observes, that the virtues attributed to this plant are at once numerous and very wonderful. He says, an infusion of the young tops is good in the jaundice; its operation is by urine, the quantity of which it considerably increases if the use of it be continued for some time. The expressed juice is a remedy for spitting of blood; and the powdered leaves are frequently given by country people for the worms, as also in gouty and rheumatic complaints, and in agues. See the preceding species.—It is common in woody thickets, hedges, and dry banks, flowering from July to September.

38. *Hypericum Dubium*; *Imperforate St. John's Wort*. Stem imperfectly four-edged; leaves blunt, without pellucid dots; calicine leaflets elliptical. In habit, size, and colour, it nearly agrees with the preceding species, but differs essentially, in having no pellucid dots apparent on the leaves, and in the calicine leaves being elliptical and obtuse. It flowers in July and August.—Native of Germany, Dauphiny, and England; growing plentifully about Sapen in Worcestershire, at Hafod in Cardiganshire, and at Downton Castle near Ludlow. See the thirty-sixth species.

39. *Hypericum Humifusum*; *Trailing St. John's Wort*. Flowers axillary, solitary; stems ancipital, prostrate, filiform; leaves smooth; root perennial, yellow, fibrous; peduncles axillary and terminating, solitary, or sometimes in pairs. It is the least of our wild *Hyperica*, scarcely inferior to any in beauty and delicacy, and is not unfrequent in gravelly pastures, in fields that have long lain untilled, on heaths, especially where the soil is moist and clayey, and sometimes in woods; flowering from June to August. See the thirty-sixth species.

40. *Hypericum Crispum*; *Curled-leaved St. John's Wort*. Stem round; leaves sessile, lanceolate, waved and toothed at the base.—Native of Calabria, Sicily, and Greece.

41. *Hypericum Linarifolium*; *Toadflax-leaved St. John's Wort*. Calices serrate, glandular; stem round, upright; leaves linear, blunt, smooth; corollas small, a little longer than the calix.—Found on the heaths near Bayonne and in Navarre.

42. *Hypericum Montanum*; *Mountain St. John's Wort*. Calices acute, serrate, glandular; stem round, upright; leaves oblong, smooth, embracing, sharpish; petals sometimes dotted towards the top.—Native of many parts of Europe, in woods and thickets, in high situations. Found in Britain, near Croydon in Surrey; in Charlton-wood, Kent; on the Bath-hills near Bungay, in Suffolk; near Stokenchurch, Henley, and Maple-Durham, in Oxfordshire; near Pershore and Eredon-hill in Worcestershire; in many parts of the west of England; in the isle of Anglesea, North Wales; near Ingleton, Cartmell Wells, and Furness Fells, in the north; and in some parts of Scotland. For its propagation and culture, see the thirty-sixth species.

43. *Hypericum Barbatum*; *Bearded-flowered St. John's Wort*. Calices and petals ciliate and dotted; leaves dotted; root perennial; flowers terminating, few, without smell.—Native of Austria, where it was found in pastures by wood-sides, flowering in June, and perfecting seeds in July and August.

44. *Hypericum Glandulosum*; *Glandulous St. John's Wort*. Calices serrulate-glandular; leaves lanceolate, glandular at the edge; stem shrubby; branches obscurely four-cornered, smooth, dichotomous; corolla pale yellow with brown dots.—It flowers from May to August, and is a native of Madeira.

45. *Hypericum Hirsutum*; *Hairy St. John's Wort*. Calices serrate, glandular; stem round, upright; leaves ovate, subpubescent; root perennial, fibrous; flowers terminating in an oblong panicle forming a kind of spike. It differs from the common *St. John's Wort* in being taller, having the stem perfectly round and hoary, and the edge of the calix beset with black glands. Linneus says that the flowers close in the night. It flowers from June to August, and is oftenest found in woods and coppices, though often found in hedges. See the thirty-sixth species.

46. *Hypericum Tomentosum*; *Woolly St. John's Wort*. Calices serrate, glandular; leaves half stem-clasping, flexuose, tomentose; stems prostrate. It flowers from July to September. It was found in stagnant water at Malta.—Native of the south of Europe.

47. *Hypericum Perfoliatum*; *Perfoliate St. John's Wort*. Stem subancipital; leaves stem-clasping, ovate; cyme with sessile flowers. It flowers in May and June.—Native of Italy.

48. *Hypericum Elodes*; *Marsh St. John's Wort*, or *St. Peter's Wort*. Stem round, creeping, villose; leaves villose, roundish; flowering branches ascending, five or six inches high; the panicle terminating, at first becomes lateral by the protrusion of the stem beyond it, and is dichotomous, rarely producing more than from five to ten flowers, which appear

in July and August, and seldom expand except in bright sunshine; petals yellow or reddish yellow, twisted spirally, or sometimes merely folded up. It has been observed in the northern parts of France, but is most common in England, where it is found in bogs; as on Hayes Common in Kent, Dersingham Moor near Lynn, with other Norfolk bogs, the Gamlingay bogs in Cambridgeshire, on Birmingham heath, and in some parts of Cornwall.

49. *Hypericum Pulchrum*; *Elegant St. John's Wort*. Calices serrate, glandular; stem round; leaves stem-clasping, cordate, smooth. The whole plant is smooth; flowering branches or peduncles round, slender, axillary, with from one to three flowers at top; petals oblong, ovate, slightly striated, on the under side tinged with bright orange, slightly serrated, and edged with the same dark-coloured glands.—Native of most parts of Europe, in woods, on heath-banks, and in hedges, especially in a clayey soil; flowering in June and July. See the thirty-sixth species. It is a hardy plant.

50. *Hypericum Nummularium*; *Moneywort-leaved St. John's Wort*. Calices serrate-glandular; leaves cordate-orbicular, smooth; stems two or three, round, simple, five or six inches long, prostrate; flowers three or five, terminating, large. It is a very small plant.—Native of Dauphiny, near the Grand Chartreuse.

51. *Hypericum Japonicum*; *Japanese St. John's Wort*. Leaves sessile, ovate, entire; stem herbaceous, four-cornered, decumbent at the base; root with capillary fibres; flowers small, peduncled, solitary, and terminating in the axils of the panicle; peduncles capillary, one-flowered, upright.—Native of Japan, where it is found flowering in June.

52. *Hypericum Erectum*; *Upright St. John's Wort*. Leaves stem-clasping, lanceolate, acute; stem round, herbaceous; flowers terminating, about three together; peduncles and pedicels filiform, like the stem, leafy, fastigate; corolla scarcely longer than the stamina.—Native of the mountains of Japan, flowering in August.

53. *Hypericum Coris*; *Heath-leaved St. John's Wort*. Calices serrate-glandular; leaves subverticillate; stem round, a long span in height; flowers terminating in a loose spike, on one-flowered peduncles, which, as well as the bractes, are full of large black glands; petals large in proportion to the plant, marked with lines. This is an elegant little evergreen, forming a pretty bush, and flowering during most of the summer.—Native of the south of Europe, and of many parts of the Levant and Crimea. It is propagated by cuttings, and may stand in the open air, with a reserve of plants, in very severe weather: but it is commonly considered a green-house plant.

*** *With two Styles.*

54. *Hypericum Mutilum*. Leaves ovate, sessile.—Native of watery places in Virginia.

55. *Hypericum Setosum*. Leaves linear; stem shrubby, four-cornered, hairy, branching like Horse-tail; flowers golden-coloured.—Native of Virginia and Carolina.

**** *With one Style.*

56. *Hypericum Revolutum*. Leaves linear-lanceolate, rolled back at the base; stamina shorter than the corolla; stem shrubby, smooth with a brown wrinkled bark; flowers terminating, solitary; germen ovate.—Native of Arabia.

57. *Hypericum Monogynum*; *Chinese St. John's Wort*. Stamina longer than the corolla; calices coloured; stem shrubby; root composed of many woody fibres striking deep into the ground; stems several, shrubby, nearly two feet high, covered with a purplish bark; leaves stiff, smooth, about two inches long; flowers terminating in small clusters, each on a short peduncle; calicine segments divided almost to the bottom, obtuse, deep purple; petals large, obtuse,

bright yellow, concave; germen ovate. It continues in flower from March to September, and may be propagated by slips from the root, or by laying down the branches. If by slips, they should be planted in the same spring on a moderate hot-bed, the layers should be made at the same time to take root by autumn, when they may be transplanted into pots, and sheltered under a frame in winter. In spring, part of these may be set in a warm border, and the others continued in pots to be screened in winter. Those plants which stand abroad, will not flower in winter like those that are sheltered in autumn.

Styles united.

58. *Hypericum Amœnum*. Terminal flowers subsolitary, sessile; leaflets of the calix ovate, acuminate; petals deflex, longer than the stamina; styles united together, of the length of the stamina. This elegant species grows to the height of about two feet or more. Every branchlet has from one to three large flowers, of a bright golden yellow; the petals turn downwards, and leave the large crown of the stamina in an upright situation, which, with the beautiful red ovate germen in the centre, gives the flower a particularly pleasing appearance.—Native of South Carolina and Georgia.

59. *Hypericum Glaucum*. Branches cylindrical; leaves oblong, cordate; leaves of the calix ovate, acute, longer than the petals; stamina equal to the petals; styles united together; flowers large.—Native of Florida.

60. *Hypericum Densiflorum*. Plant very branchy; little branches somewhat cylindrical; leaves linear, lanceolate; stamina and styles united together, and shorter than the petals; flowers in very abundant and close panicles.—Found on the ridges and in the savannas of the Virginian mountains.

61. *Hypericum Galioides*. Branchlets tetragonal; leaves linear, sessile, revolute on the margin. About two feet high when in flower.—Found from New Jersey to Carolina, in moist sandy places near rivulets.

62. *Hypericum Triplinerve*. Plant erect, somewhat branchy; leaves linear; flowers racemose-paniculated; corolla unequal; calices acute. It has pale yellow flowers.—Found upon the banks of the Ohio.

63. *Hypericum Sphærocarpum*. Plant erect, very glabrous; leaves oblong; panicles naked; dichotomous; styles united; capsules globose.—Native of Kentucky.

64. *Hypericum Procumbens*. Leaves linear; leaflets of the calix oblong, lanceolate, acute; stamina shorter than the corolla; styles united; calix as large as the corolla.—Native of the dry sunny hills of Kentucky.

Hyphydra; a genus of the class Monœcia, order Gynandria.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth one-leafed, three-parted; lobes obovate, concave, curved in at top, smooth. *Corolla*: none. *Stamina*: filamenta six, capillary, long, inserted above the germen at the corners; antheræ roundish. *Pistil*: germen empty, inflated, membranaceous, hexagonal, truncate at top; style capillary, the length of the stamina; stigma none. *Female Flowers*. *Calix*: none. *Corolla*: none. *Stamina*: none. *Pistil*: germen roundish, with three streaks; style triangular; stigmas three, acute. *Pericarp*: capsule membranaceous, one-celled, three-valved. *Seed*: single, ovate, striated. *ESSENTIAL CHARACTER*. *Male*. *Calix*: one-leafed, three-parted. *Corolla*: none. *Stamina*: six, inserted above the germen. *Female*. *Calix* and *Corolla*: none. *Style*: triangular, with three stigmas; capsule one-celled, three-valved. *Seed*: single.—The only known species is,

1. *Hyphydra Fluvialis*. Stems and branches slender; leaves alternate, long, narrow, lanceolate, smooth, acuminate, marked with lines, ciliate, embracing. Some of the stems

are erect, others decumbent, the last of which throw out roots; flowers in capitate bundles, each composed of a male flower, involved in a long sharp bracte, ciliate at the edge, and a female flower included with three bractes of the same form: they are axillary, and on a slender peduncle.—This little plant is a native of Guiana, and grows three or four feet under water, flowering in February.

Hypnum; a genus of the class Cryptogamia, order Musci.—GENERIC CHARACTER. *Capsule*: oblong; peristomium double, outer with sixteen broadish teeth, inner membranaceous, equal, lacinated; segments broadish, with capillary ones interposed. *Males*: gemmaceous on different plants. *Or thus*. *Peduncle*: from a lateral tubercle, fenced with scales; capsule outer, fringed with sixteen teeth. *Male*: a bud, generally on a different plant. This is a very numerous genus of Mosses, which has been thrown into seven divisions by Dr. Withering, in order to facilitate the investigation of the species. His arrangement contains seventy species. Hudson's *Flora Anglica*, forty; and there are also fifty species in the fourteenth edition of the *Systema Vegetabilum*, besides the new species discovered by Dickson, &c.

Hypochoeris; a genus of the class Syngenesia, order Polygamia Æqualis.—GENERIC CHARACTER *Calix*: common roundish, imbricated, ventricose at the base; scales lanceolate, acute. *Corolla*: compound imbricated, uniform; corollets hermaphrodite, equal, numerous; proper one-petalled, ligulate, linear, truncate, five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindrical, tubular. *Pistil*: germen ovate; style filiform, the length of the stamina; stigmas two, reflex. *Pericarp*: none. *Calix*: converging, globular, acuminate. *Seeds*: solitary, oblong; down feathered, stipitate. *Receptacle*: chaffy; chaffs lanceolate-linear, the length of the seeds. *Observe*. In the third and fifth species the seeds of the disk have a stipitate down, but in those of the ray it is sessile. *ESSENTIAL CHARACTER*. *Calix*: subimbricate. *Down*: feathered. *Receptacle*: chaffy.—The species are,

1. *Hypochoeris Helvetica*; *One-flowered Hypochoeris*. Stem simple, leafy, one-flowered; leaves lanceolate, toothed; root perennial, almost fusiform, thickish, somewhat woody, sometimes divided, dark brown on the outside, white within, milky, putting up one, sometimes two or three stems, among abundance of radical leaves; flowers very large, from erect spreading; corollets very numerous, long, deep yellow, five-toothed, from erect spreading, with yellowish white villose hairs at the base.—Native of the mountains of Carinthia, Dauphiny, and several parts of the Alps.

2. *Hypochoeris Maculata*; *Spotted Hypochoeris*. Stem almost naked; branch solitary; leaves ovate, oblong, entire, toothed; root thick and long, abounding with milky juice, as does the rest of the plant. The flower opens at six in the morning, and closes at four in the afternoon; seeds wrinkled. The leaves are boiled in Smoland, and eaten like cabbage. The country people believe the plant to be a cure for tetters, and other cutaneous eruptions, possibly on account of its spotted leaves, which, though bitter, are eaten greedily by ruminating animals. It flowers in July, is perennial, and a native of many parts of Europe. Though not common in England, it is found on the Gogmagog hills and Newmarket heath, in Cambridgeshire; on Bernack-heath in Northamptonshire; and about Malham Cove, and Cartmell Wells, and near Settle, in Yorkshire.

3. *Hypochoeris Glabra*; *Smooth Hypochoeris*. Root annual, the thickness of a crow-quill, tapering, furnished with few fibres, pale brown; peduncles scaly, a little thickened under the flower, which is very small. It may be distin-

guished by the smallness of the flowers, not exceeding the size of a silver threepence, while the heads containing the seeds are altogether as large in proportion to the size of the plant. The flowers are open from about nine in the morning till about one or two in the afternoon. It delights in a sandy soil and exposed situation, and flowers in June.

4. *Hypochoeris Radicata*; *Long-rooted Hypochoeris*. Leaves runcinate, obtuse, rugged; stem branched, naked, even; peduncles scaly; root perennial, the thickness of the little finger, running deeply into the earth, generally simple, of a whitish colour, and milky within; flowers large, closing at three in the afternoon. It is distinguished from *Leontodon Autumnale*, by the length of the root from whence it derives its trivial name. In barren soils it occurs of a much smaller size, five or six inches high, with an unbranched stem, or with one flower, almost sessile on the side. It is common on dry banks, heaths, and pastures, flowering from May to September; and in the early part of summer is a conspicuous plant, and is called *Hawkweed*, in common with many others. Dr. Withering has named it *Cat's Ears*.

5. *Hypochoeris Minima*; *Least Hypochoeris*. Leaves sinuate-lyrate; stem with scaly appendices at top; root down-right, two, or three inches long; stem naked, simple, one-flowered, a palm in height, smooth; flower small, equal.—Native of Italy and Naples, on volcanic ground, particularly the Solfaterra, flowering from May to June.

Hypoxis; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: glume two-valved. *Corolla*: one-petalled, superior; limb six-parted; segments ovate, oblong, spreading, permanent. *Stamina*: filamenta six, very short, capillary; antheræ oblong, shorter than the petals. *Pistil*: germen inferior, turbinate; style filiform, the length of the stamina; stigma bluntish. *Pericarp*: capsule somewhat oblong, narrower at the base, crowned with the permanent corollas, three-celled, three-valved; according to Gærtner, valveless; seeds very many, roundish. ESSENTIAL CHARACTER. *Calix*: a two-valved glume. *Corolla*: six-parted, permanent, superior. *Capsule*: narrower at the base.—The species are,

1. *Hypoxis Erecta*; *Upright Hypoxis*. Hairy, with ovate capsules: root tufted, with fleshy branched fibres; stems two or three, shorter than the leaves, upright, round, hairy, reddish above, each bearing one upright flower; corolla externally green and hairy, with a red rib, internally concave, yellow, smooth, without veins or nerves. It flowers in June, and is a native of North America.

2. *Hypoxis Decumbens*; *Trailing Hypoxis*. Hairy, with club-shaped capsules: bulb roundish, fleshy, brown, putting out fibres from the side; peduncles radical from the sheaths among the leaves; seeds wrinkled, black. The roots came accidentally into Mr. Miller's hands among some Allspice plants, in 1755. It flowers most part of the year.—Native of Jamaica, in sandy fields, among the mountains. It will not thrive well in England, unless the pots be plunged into a hot-bed of tanner's bark, and the air kept up to the heat assigned for Ananas. In this situation the plants will thrive; produce plenty of flowers, and perfect their seeds, which, if suffered to scatter on the pots, will produce plenty of young plants; or, if they be sown in pots soon after they be ripe, and planted into the tan-bed, will come up in about six weeks, and, when they are fit to transplant, may be treated in the same manner as the old plants.

3. *Hypoxis Spicata*; *Spiked Hypoxis*. Upright: leaves ensiform, falcate, smooth; flowers in spikes; root composed of capillary fibres in bundles; flowers from the middle to the top of the spikes, alternate, remote, very many; capsule and

rachis very rough with hairs. It flowers in May and June, and is a native of Japan.

4. *Hypoxis Plicata*; *Plaited-leaved Hypoxis*. Scape one-flowered, three-sided; leaves lanceolate, plaited, villose; bulb globular; corolla yellow.—Native of the Cape of Good Hope. For the treatment of this, and of the fifth, sixth, seventh, eighth, eleventh, twelfth, and thirteenth species, see *Albuca*.

5. *Hypoxis Stellata*; *Spotted-flowered Hypoxis*. Scape one-flowered; leaves linear, striated; petals spotted. This is a beautiful little bulbous plant, with a dark spot at the claws of the petals; leaves like those of *Narcissus*, the length of the scape, which is sheathed below the middle.—Native of the Cape of Good Hope. See the preceding species.

6. *Hypoxis Aquatica*; *Aquatic Hypoxis*. Leaves linear; scapes umbelled, or one-flowered; flowers in some solitary, hermaphrodite, in others umbelled, male.—Found in watery ditches at the Cape of Good Hope. See the fourth species.

7. *Hypoxis Serrata*; *Channel-leaved Hypoxis*. Leaves channelled, smooth, ciliate, serrate; scapes one-flowered. It flowers in July.—Native of the Cape of Good Hope. See the fourth species.

8. *Hypoxis Villosa*; *Hairy Hypoxis*. Leaves linear, ensiform, villose; stigma simple, three-cornered, acute; capsule small, narrower at the base, so as to be almost club-shaped.—Native of the Cape of Good Hope. See the fourth species.

9. *Hypoxis Fascicularis*. Tube of the flowers very long.—Native of Syria, near Aleppo.

10. *Hypoxis Sessilis*. Hairy, stemless: fructifications sub-radical; leaves linear, straight; petals pointed, plaited, three outer broader, green, hairy: it flowers at the latter end of June.—Native of Carolina. Seeds round, black, and shining.

11. *Hypoxis Minuta*. Leaves three-sided, fleshy, smooth; scapes bifid; bulb conical, large in proportion to the plant; corolla spreading, snow-white; filamenta shorter than the corolla.—Native of the Cape of Good Hope. See the fourth species.

12. *Hypoxis Ovata*. Leaves ovate-lanceolate, entire, smooth; scapes one-flowered; flower white, and pretty.—Found at the Cape of Good Hope. See the fourth species.

13. *Hypoxis Alba*. Leaves cylindric, smooth; scapes subdifid; petals unspotted.—Found by Thunberg at the Cape of Good Hope. See the fourth species.

14. *Hypoxis Aurea*. Stemless, hairy: scape one-flowered; capsules oblong; leaves awl-shaped, channelled, reflex, half a foot long, clustered; corolla bell-shaped, equal, golden coloured within, greenish on the outside, hairy.—Native of Cochin-china, where it was found on a sandy hill called *Sou Koung*.

15. *Hypoxis Graminea*. Scape four-flowered; leaves very long, shorter than those of grass, very narrow, and double the length of the scape.—Found from New Jersey to Carolina, in dry sandy fields and woods.

Hyptis; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth turbinate, half five-cleft, permanent; segments lanceolate, acute, almost equal, upright. *Corolla*: one-petalled, ringent; tube funnel-form; throat widened; limb spreading very much, resupinate; upper lip, which is the lower in situation, trifid; lateral segments ovate, acute, the middle one roundish, concave, obtuse; lower lip (in situation the upper) semibifid; segments semiovate, flat, acute. *Stamina*: filamenta four, awl-shaped, erect, of which two are shorter; antheræ twin, hanging down. *Pistil*: germen four-cleft; style filiform;

stigma bifid or simple. *Pericarp*: none. *Calix*: fostering the seeds. *Seeds*: four. **ESSENTIAL CHARACTER.** *Calix*: turbinate. *Corolla*: with a very spreading border, lower lip semibifid. *Antheræ*: hanging down.—The species are,

1. *Hyptis Verticillata*. Leaves lanceolate; flowers in whorls. This shrub is ten feet high, with one or two upright woody stems; corolla white.—Native of St. Domingo.

2. *Hyptis Capitata*. Leaves ovate; flowers in heads; stems suffruticose, two or three feet high or more, becoming woody, commonly four-cornered, brown; branches annual, herbaceous, subdivided; peduncles axillary, solitary, four-cornered, slender, from two to three inches long, bearing at the end numerous flowers collected closely into a semi-globular head. The petal is white, with sometimes a tinge of flesh-colour: the whole plant is inodorous. *Antheræ* yellow.—Native of St. Domingo, where it flowers in December and January.

Hyssop. See *Hyssopus*.

Hyssop Hedge. See *Gratiola*.

Hyssopus; a genus of the class Didynamia, order Gynospemia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, cylindrical, oblong, striated, acutely five-toothed, permanent. *Corolla*: one-petalled, ringent; tube cylindrical, slender, the length of the calix; throat inclined; upper lips straight, flat, short, roundish, emarginate; lower lip trifid; lateral segments shorter, blunt, the middle one crenate, obcordate, acute, with distant lobes. *Stamina*: filamenta four, upright, longer than the corolla, distant; the two upper ones shorter, but the two longer nearer to the lower lip; *antheræ* simple. *Pistil*: germen four-parted; style filiform, under the upper lip, and of the same length; stigma bifid. *Pericarp*: none; calix fostering the seeds. *Seeds*: four, subovate. **ESSENTIAL CHARACTER.** *Corolla*: lower lip with a small middle crenate segment; stamina straight, distant.—The species are,

1. *Hyssopus Officinalis*; *Common Hyssop*. Spikes directed one way; leaves lanceolate; height a foot and half; stems first square, afterwards round, with small sessile leaves in pairs on their lower part, and seven or eight very narrow erect leaves or bractes, springing from the same joint; on the upper part, flowers in whorls, the lower ones half an inch apart, the upper almost joined; *antheræ* twin; seeds black. There are many varieties of this plant: the leaves vary in colour as well as the flowers, sometimes being white striped with green, or half green and half white; others with the leaves wholly yellow, or but a little green in them: sometimes yellow, as the Gold Hyssop, which, Parkinson says, was so pleasant a colour in his time, that it provoked many gentlemen to wear them in their heads and on their arms, with as much delight as many fine flowers can give. The leaves are also sometimes curled or cramped at the edges, so that each leaf seems to be composed of many. It also varies in the stem, and in the scent, which is sometimes stronger than common, approaching to that of musk. Ray enumerates nine varieties. The roots will abide many years. The whole plant has a strong aromatic smell. It flowers in July and August, and ripens seed in

September. Meyrick remarks, that it is a plant of very considerable virtues, particularly in disorders of the breast and lungs. A strong infusion, or tea, made with the young tops, is not particularly unpleasant, and is the best mode of using it. There are few better medicines for coughs, hoarsenesses, and obstructions of the breast. The infusion, made into a syrup with honey, is excellent for the same purposes. The tea, when plentifully taken, removes obstructions of the viscera; and operates powerfully by urine. It should be gathered when just beginning to flower. The green herb bruised, with the addition of a little sugar, is said to heal cuts and green wounds with great expedition. This plant, with all its varieties, may be propagated either by seeds or cuttings: if by seeds, they must be sown in March, upon a bed of light sandy soil, and when the plants come up, they should be transplanted out to the places where they are to remain, placing them at least a foot asunder each way; but if they are designed to abide in those places for a long time, two feet distance will be small enough, for they grow pretty large, especially if they are not frequently cut to keep them within compass. If you would propagate them by cuttings, they should be planted in April or May, on a border where they may be defended from the violent heat of the sun; and being frequently watered, they will take root in about two months; after which they may be transplanted where they are to continue, managing them as was before directed for the seedling plants. They are very hardy, and will endure the cold of our winters in the open air, provided they are planted in a dry undunged soil; for a rich soil causes them to grow so luxuriantly in summer that they are the less able to resist the cold of the winter, so that those plants which we frequently find growing out of the joints of old walls, will better resist the severest frost, and be much more aromatic, than those which flourish in a rich soil.

2. *Hyssopus Lophanthus*; *Mint-leaved Hyssop*. Corollas resupinate; lower stamina shorter than the corolla; leaves cordate; root strong, fibrous, perennial, sending out many square stalks, which divide into smaller branches; flowers produced at each joint in small clusters; corollas blue. The flowers appear in June and July, and the seeds ripen in September.—Native of Siberia. Both this and the following species are very hardy, and may be easily propagated by sowing seeds in autumn, for those sown in the spring often lie a year in the ground before they vegetate. When the plants come up, keep them clean from weeds, and thin them where they are too close. The following autumn transplant them where they are to remain, and the roots will last several years.

3. *Hyssopus Nepetoides*; *Square-stalked Hyssop*. Stem sharp, quadrangular; root perennial; leaves oblique, heart-shaped, serrate, acute, on short footstalks; flowers yellow, in close thick spikes four or five inches long; upper lip of the corolla divided into two roundish segments. There is a variety with purple stalks and flowers, the leaves on longer footstalks, and the spikes of flowers thicker. Gouan remarks, that this plant has the appearance of *Galeopsis*.—Native of Virginia and Canada. See the preceding species.

J A C

JACA Tree. See *Artocarpus*.

Jack in a Box. See *Hernandia*.

Jack by the Hedge. See *Erysimum Alliaria*.

Jacquinia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved; leaflets roundish, concave, permanent. *Corolla*: one-petalled; tube bell-shaped, ventricose, longer than the calix; border ten-cleft; divisions roundish, of which the five

J A C

interior ones are shorter. *Stamina*: filamenta five, awl-shaped, arising from the receptacle; *antheræ* spear-shaped. *Pistil*: germen ovate; style the length of the stamina; stigma headed. *Pericarp*: berry roundish, acuminate, one-celled. *Seed*: single, roundish, cartilaginous. **ESSENTIAL CHARACTER.** *Corolla*: ten-cleft. *Stamina*: inserted into the receptacle. *Berry*: one-seeded.—These plants must be kept in the bark-stove, giving them little water in winter, and in

warm weather plenty of fresh air. They are raised from seeds procured from the country where they grow naturally, and afterwards from cuttings, but it is with difficulty that these take root.—The species are,

1. *Jacquinia Armillaris*; *Obtuse-leaved Jacquinia*. Leaves obtuse, coriaceous; flowers in racemes; berries four-seeded or thereabouts. This is a very elegant upright shrub, seldom more than four or five feet high; flowers small, stiffish, white, smelling like Jasmine, and retaining their sweet scent several days; peduncles scattered, spreading, one-flowered; berry roundish, smooth, the size of a large pea, of a reddish orange colour, and containing an orange-coloured pulp; seeds four, sometimes (but seldom) three or five, ovate, smooth, shining, cartilaginous, brownish yellow. The berries are eaten by small birds, and the seeds are strung for bracelets by the Caribbees, whence the French in the islands call this shrub *Bois Bracelets*, and Linneus gives it the trivial name of *Armillaris*; the Spaniards call it *Barbasco*, or *Verbascum*.—It flowers in February and March, and is a native of South America and the West India islands, where it is found on the calcareous rocks of Jamaica, Curaçoa, Martinico, Carthagera, &c.

2. *Jacquinia Venosa*; *Vein-leaved Jacquinia*. Leaves ovate, lanceolate, veined, submembranaceous.—Native of the West Indies.

3. *Jacquinia Ruscifolia*; *Prickly Jacquinia*. Leaves lanceolate, acuminate. This is a shrub three feet in height, with all the habit of the preceding: it differs in having the leaves lanceolate, acuminate, pungent, extremely stiff, and shorter; the peduncles are as pendulous as in that, and one-flowered.—Native of South America.

4. *Jacquinia Linearis*; *Linear-leaved Jacquinia*. Leaves linear, acuminate. This is a shrub two feet in height, very much branched, of the same habit with the two preceding, but not so neat; peduncles one-flowered, solitary, terminating, pendulous, shorter than the leaves; flowers stiffish, and without any smell; petals white, with all the segments convex, the outer ones spreading, the inner almost erect; berries yellow.—Native of the island of St. Domingo, about Port au Prince, on the coast, flowering and fruiting in January.

Jasione; a genus of the class Syngenesia, order Monogamia.—GENERIC CHARACTER. *Calix*: perianth common, ten-leaved, alternate; leaflets inferior, narrower, including very many flowers on very short peduncles, permanent; perianth proper, five-cleft, superior, permanent. *Corolla*: proper one-petalled, regular, deeply five-cleft; divisions lanceolate, upright. *Stamina*: filamenta five, awl-shaped, short; antheræ five, oblong, connected at the base. *Pistil*: germen roundish, inferior; style filiform, length of the corolla; stigma bifid. *Pericarp*: capsule roundish, five-cornered, crowned with the proper calix, subbilocular, gaping at the tip with a round hole; partition divided at the axis. *Seeds*: many, subovate; receptacle subglobose, pedicelled, free, in the base of the capsule. *Observe*. The central floscules are often abortive, with an undivided club-shaped stigma. ESSENTIAL CHARACTER. *Calix*: common ten-leaved; corolla five-petalled, regular; capsule inferior, two-celled.—The only known species is,

1. *Jasione Montana*; *Mountain Jasione*, or *Hairy Sheep's Scabious*. Root annual, rigid, whitish, and fibrous; stems many, erect or procumbent, from a span to a foot in height, or more, somewhat rigid, beset with rough short hairs, angular, striated, green, often tinged with purple; for something more than one-third of their height, they are clothed with numerous leaves, which are linear or linear lanceolate, waved at the margin, bluntish at the end, hairy on both

surfaces; corolla blue, sometimes varying to white; stigma club-shaped, purple. Linneus remarks, that the leaves are obscurely serrated. Leers asserts that the calix has constantly twenty leaflets, in four rows, subserrated, the outer ones gradually larger; the antheræ are at first almost wholly united, but when the pollen is evacuated, they spread, and are joined only at the base; the central florets are barren, with the stigma club-shaped, quite entire, having pollen scattered over it, and not villose; the capsules on very short pedicels, and never ripen; the lateral florets in great numbers are fertile; they have also a club-shaped stigma, which afterwards becomes bifid; because the antheræ of these have evacuated their pollen before the stigma bursts, it seems probable that the fecundation is made by the antheræ of the barren florets; the styles of the barren florets are all upright, but those of the fertile florets are bent down, for the easier reception of the pollen. In the above curious account of the process of fecundation, the botanist cannot but remark the affinity it bears to the genuine plants of the class Syngenesia, where Linneus placed it, and from whence modern reformers have removed it. Its general appearance so resembles that of a scabious, that it is often taken for one by unskilful botanists. It varies much in size, and on the sea-coast of Cornwall is only about an inch high when full grown, and the whole plant is very hairy. The younger Linneus mentions a variety with perennial roots in his *Supplement*, its native place unknown; his father informs us that bees are particularly fond of the flowers of this plant, the whole of which is milky, and sometimes eaten by sheep. Ray calls it *Rampions* with scabious-like heads; and *Withering*, *Scabious Sheep's-bit*. It flowers from June to August; and is common on dry sandy grounds, heaths, and hilly pastures.

Jasminum; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubulated, oblong; mouth five-toothed, upright, permanent. *Corolla*: one-petalled, salver-shaped; tube cylindric, long; border five-parted, flat. *Stamina*: filamenta two, short; antheræ small, within the tube of the corolla. *Pistil*: germen roundish; style filiform, length of the stamina; stigma bifid. *Pericarp*: berry oval, smooth, two-celled or two-capsuled. *Seeds*: two, large, ovate-oblong, arillated, convex on one side, flat on the other. *Observe*. The shape of the flower varies as to acuteness or obtuseness; the berry is in some simple, in others dicoccous. ESSENTIAL CHARACTER. *Corolla*: salver-shaped; berry dicoccous. *Seeds*: solitary, arillated.—The species are,

1. *Jasminum Sambac*; *Arabian Jasmine*. Leaves opposite, simple, elliptic, ovate and subcordate, membranaceous, opaque; branchlets and petioles pubescent; calicine segments awl-shaped. It rises with a winding stalk to the height of fifteen or twenty feet, sending out small branches. Tube of the corolla narrow, about half an inch long, cut at the top into eight obtuse segments, which spread out quite flat; the flowers are of a pure white, and have a most agreeable odour, somewhat like orange flowers, but sweeter; when fully blown, they drop out of their cups on being shaken, and frequently fall out in the night, changing soon to a purplish colour; the plants continue flowering great part of the year, when they are kept in a proper temperature of warmth. This beautiful plant, so much esteemed for its highly odoriferous flowers, is a native of the East Indies, where it is much cultivated, as well as in China and in the West Indies.—There are several varieties of it in those countries; we have it both with single and double flowers, and also with large double flowers, which last grows naturally at Malabar, and, being very fragrant, the women there string its flowers

round their necks by way of ornament. These plants are frequently imported from Italy by the Italian gardeners who bring orange-trees for sale; but as they are always grafted upon stocks of the Common Jasmine, and do not keep pace with the growth of the stock, they become very unsightly; besides, the stocks are very apt to shoot from the bottom, and if these shoots be not constantly rubbed off, they will starve the graft. The best method therefore to obtain plants is by layers or cuttings, the former is the surest method, for unless the cuttings be very carefully managed, they will not take root; and the stems being pliable, may easily be brought down, and laid in pots filled with a soft loamy soil, plunged into a hot-bed of tan. If the branches be laid down in the spring and carefully watered, they will put out roots by autumn, when they should be cut from the old plants, and each transplanted into a separate small pot, and then plunged into the tan-bed, where they should be shaded from the sun till they have taken new root. Cuttings may be planted from May to August, in pots filled with the same earth, and plunged into a moderate hot-bed of tanner's bark. The pots should be large enough to contain ten or twelve cuttings, and should be closely covered with bell or hand glasses to exclude the air, shaded from the sun in the heat of the day, and gently refreshed with water when the earth is dry; they will have taken root by August, when they may be transplanted into separate pots, and treated in the same way as the layers. This plant may be preserved in a moderate degree of warmth, but will thrive much better in the bark-stove, and produce a greater quantity of flowers; as the leaves continue all the year, it will make a fine appearance at all seasons in the stove, especially as it flowers during the greatest part of the year.

2. *Jasminum Glaucum*; *Glaucous-leaved Jasmine*. Leaves opposite, simple, lanceolate, shining; calicine segments awl-shaped. This is a shrub with round, even, opposite branches; peduncles terminating, three-cleft or three-flowered; flowers larger than those of Common Jasmine. It flowers in August.—Native of the Cape of Good Hope.

3. *Jasminum Capense*. Leaves opposite, ternate, ovate, acuminate; stem erect; leaves angular.—Found by Thunberg at the Cape of Good Hope.

4. *Jasminum Azoricum*; *Azorian Jasmine*. Leaves opposite, ternate; leaflets ovate and subcordate, waved; branchlets smooth, round; segments of the corolla equal to the tube. It has long slender branches which require support, and may be trained twenty feet high; flowers terminating in loose bunches; the corolla is of a clear white, and has a very agreeable scent. It flowers from May to November.—Native of the Azores. This species is rather hardy, and only requires to be sheltered from very severe frost. It is a green-house plant, and will live against a warm wall if dung be laid to the roots, and a mat laid over it in frosty weather. It deserves a place in every green-house, for the leaves being of a shining green, make a good appearance all the year, and the flowers affording a fine scent, and continuing long in succession, render it very valuable. It is propagated in the same manner as the twelfth species; which see.

5. *Jasminum Angulare*. Leaves opposite, ternate; leaflets ovate, obtuse; branchlets angular, both they and the petioles villose; peduncles axillary, three-flowered; branches opposite, round, with an ash-coloured bark; flowers pedicelled; tube of the corolla almost an inch and a half long.—Native of the Cape of Good Hope.

6. *Jasminum Auriculatum*. Leaves opposite, ternate, on the flowering branchlets, simple; calices angular; branches round and pubescent; panicle terminating, two inches long;

peduncles trichotomous, fastigate, sometimes solitary, opposite; from the last axils twice trifid, corolla an inch long, smooth.—Native of Malabar.

7. *Jasminum Flexile*. Smooth: leaves opposite, ternate; racemes axillary, brachiate; stem climbing; branches round; partial peduncles opposite, spreading very much, one-flowered or three-flowered; flowers pedicelled.—Native of the East Indies.

8. *Jasminum Didymum*. Smooth: leaves opposite, ternate; leaflets ovate-lanceolate; racemes axillary; branches round, smooth: this seems to be a climbing shrub.—Native of the Society Isles in the South Seas.

9. *Jasminum Simplicifolium*. Leaves opposite, ovate, lanceolate, simple.—Native of the Friendly Islands in the South Seas.

10. *Jasminum Fruticans*; *Common Yellow Jasmine*. Leaves alternate, ternate; leaflets obovate and wedge-shaped, obtuse; branches angular; calicine segments awl-shaped. It has weak angular branches which require support, and will rise to the height of eight or ten feet, if planted against a wall or pale; the calix is deeply five-cleft.—Native of the south of Europe, and the Levant. Besides the common name of Yellow Jasmine, Parkinson has those of Shubby Trefoil and Make-bate, which are now obsolete. This plant was formerly more cultivated than at present, for as the flowers are destitute of scent, few persons regard them; besides, it often produces so many suckers as to become troublesome; and as it cannot be kept in order for standards, it is seldom introduced into gardens at present, but is easily propagated by suckers or layers.

11. *Jasminum Humile*; *Italian Yellow Jasmine*. Leaves alternate, acute, ternate and pinnate; branches angular; calicine segments very short. This species also was annually brought from Italy by those who imported orange-trees; the flowers are generally larger than those of the preceding, but have very little scent, and are seldom produced so early in the season: it flowers from July to September; native country unknown. This is less hardy than the preceding species, but will endure the cold of our ordinary winters in a warm situation; it may be propagated by laying down the tender branches, or by budding or inarching it upon the common yellow sort; the latter mode is preferable for obtaining hardier plants: it should be planted against a warm wall, and in severe winters will require to be sheltered with mats; it must be dressed and pruned in the same way as the thirteenth species; which see.

12. *Jasminum Odoratissimum*; *Yellow Indian Jasmine*. Leaves alternate, bluntish, ternate and pinnate; branches round; calicine segments very short; it rises with an upright woody stalk eight or ten feet high, covered with a brown bark; the flowers are produced in bunches at the ends of the shoots; the corolla has a long slender tube, and the segments are blunt and spreading; the whole is of a bright yellow colour, and has a most grateful odour; the flowers come out from July to October and November, and are frequently succeeded by oblong oval berries, which turn black when ripe, and have each two seeds; it is propagated either by the seeds, or by laying down the tender branches; if by seeds, which it sometimes produces in England, make a moderate hot-bed in the spring, into which plunge some small pots, filled with fresh light earth, and in a day or two after, when you find the earth in the pots warm, put in the seeds, four in each pot, covering them about an inch thick with the same light earth, which, when dry, must be frequently refreshed with water in small quantities; about six or eight weeks after sowing, the plants will appear above ground, at

which time it will be necessary to remove the pots into another fresh hot-bed, of a moderate temperature, in order to bring the plants forward; water them as often as is necessary, and in the great heat of the day the glasses should be tilted pretty high, and shaded with mats, to prevent the plants from being scorched with heat. About the middle of May begin to harden them to the open air, by taking off the glasses when the weather is warm: but this must be cautiously done, for exposing them at first to a very hot sun would greatly injure them. The glasses should be taken off first in warm cloudy weather, or during gentle showers, and so gradually inure them to bear the sun. In June take the pots out of the hot-bed, and remove them to some well-sheltered situation; where they may remain until the beginning of October; at which time they must be carried into the green-house, observing to place them where they may enjoy as much free air as possible when the windows are opened, as well as stand clear from the branches of other plants. During winter they will often require watering sparingly; and in March should be each removed into a separate pot, observing not to take the earth from their roots. If they be then plunged into a fresh moderate hot-bed, it will greatly facilitate their rooting afresh: when rooted, they must have plenty of air; for if too much drawn, they will become weak in their stems, and incapable of supporting their heads, which is a great defect in these trees. In the middle of May remove them into the open air, to harden; observing, as before directed, to place them in a situation that is defended from strong winds, which are injurious to these plants, especially when they are young. In winter, house them as before, and continue the same care, with which they will thrive very fast, and annually produce great quantities of flowers. They are pretty hardy, and only require to be protected from hard frosts in winter: and as they are much hardier than the Spanish, would probably live in the open air if planted against a warm wall; but there is this difference between the two plants, that these have large, thick, evergreen leaves, so that if they were covered with mats, as is directed for the Spanish Jasmine, the leaves would rot and decay the shoots, but as these will only require to be covered in extreme frost, if their roots are well mulched, and a mat or two hung over them in ordinary frosts, it will be sufficient; and these mats being either rolled up or taken quite off in the day, there will be no great danger of their being hurt, which can only proceed from their being too long closely covered. In the spring they should be pruned, and have all their decayed branches removed; but none of the other branches must be shortened, as is directed for the Spanish sort, for the flowers of this kind are produced only at the extremity of the branches; hence if the branches be shortened, the flowers will be cut off, and as the branches are of a more ligneous substance than the other, they will not produce shoots strong enough to flower the same year. To propagate this plant from layers, lay down the shoots in March, and if you give them a little cut at the joint, as is practised in laying carnations, it will promote their rooting, observing to refresh often with water when the weather is dry; and the plants will be rooted by the succeeding spring fit to be transplanted, when they must be placed in pots filled with light earth, and managed as was before directed for the seedling plants. This sort is frequently propagated by inarching the young shoots into stocks of the Common Yellow Jasmine, but the plants so raised do not grow so strong as those which are upon their own stock; besides, the Common Yellow Jasmine is very apt to send out a great number of suckers from the root, which, we have before observed, renders the plants

unsightly, and, if not taken off as fast as they are produced, will rob the plants of their nourishment.

13. *Jasminum Officinale*; *Common White Jasmine*. Leaves opposite, pinnate; leaflets acuminate; buds almost upright; stem shrubby, weak, climbing, round, smooth, branching; peduncles few-flowered; corolla white, odorous; they are the only part of the plant used in medicine. An infusion of five or six ounces of them picked clean from the leaves, in a quart of boiling water, being strained off and boiled into a syrup, with the addition of a sufficient quantity of honey, is an excellent medicine in coughs, hoarsenesses, and other disorders of the breast. There is also an oil, or, as it is commonly called, an essence, prepared from these flowers, which is used in perfumes, but seldom applied to any medical purposes. We are not certain as to the native country of our Common White Jasmine. Though it has been long inured to our climate, so as to thrive and flower extremely well, yet it never produces any fruit in England: it is probably a native of the East Indies. The name Jasmine, has been corrupted into Jessamine, Gelsemine, Jessmia, Jessamy, and Gesse. The Germans call it *Jasmin*, *Jesmin*, *Schasmin*, *Schelsemine*, *Viobreben*; the Dutch, *Jasmin*; the Swedish, Danish, and French, *Jasmin*; the Italians, *Gelsomino*; the Spaniards, *Jazmin*; the Portuguese, *Jasmin*, *Jesmin*, *Jasmi-neiro*; and the Arabians, *Jasmin*, *Kajan*. It is easily propagated by laying down the branches, which will take root in one year, and may then be cut from the old plant, and set where they are intended to remain. It may also be propagated by cuttings, which should be planted early in autumn, and in severe winters the surface of the ground between them should be covered with tan, sea-coal, ashes, or sawdust, which will prevent the frost from penetrating deep into the ground, and preserve the cuttings: pease-haulm, or other light covering, should be laid over them, where the former cannot be procured; but these coverings must be removed when the weather is mild, for they will keep off the air, and occasion damps, which often destroy them. When these plants are removed, they should be planted where they are designed to be continued, which should be either against some wall, pale, or other fence, where the flexible branches may be supported; for although it is sometimes planted as a standard, and formed into a head, yet it will be very difficult to keep it in any handsome order; or if you do, you must cut off all the flowering branches, for the flowers are always produced at the extremity of the same year's shoots, which, if shortened before the flowers are blown, will entirely deprive the trees of flowers. They should be permitted to grow rude in the summer, for the reason before given; nor should you prune or nail them until the latter end of March, when the frosty weather is past, for if the frost should set in after their rude branches are pruned off, and the stronger ones be exposed to it, they will hardly escape being killed: but on the other hand, as this plant is very backward in shooting, there will be no danger of injuring it by late pruning. There are two varieties with variegated leaves, one with white, and the other with yellow stripes, but the latter is the most common: these are propagated by budding them on the plain Jasmine; and it often happens that the buds do not take, but yet communicate their gilded miasma to the plants, so that in a short time after, many of the branches, both above and below the places where the buds have been inserted, have been thoroughly tinged; and in the following year, distant branches, which had no other communication with those which were budded than by the root, have been as completely tinged as any of the nearer branches, so that the juices must have descended

into the root. These two striped sorts should be planted in a warm situation, especially the white striped; for they are much more tender than the plain, and are very subject to be destroyed by great frosts when exposed. They should have a south or south-west aspect, and in very severe winters must have their branches covered with mats or straw, to prevent their being killed. The yellow striped is not so tender, and may be planted against walls to east or west aspects: but neither of these are so much esteemed as formerly.

14. *Jasminum Grandiflorum*; *Spanish or Catalonian Jasmin*. Leaves opposite, pinnate; leaflets bluntnish; buds horizontal. It has much stronger branches than the preceding sort, of which it was once supposed to be a mere variety: the leaflets are placed closer, and are of a lighter green; the side ones are obtuse, but the odd one ends in an acute point. The flowers are axillary, on peduncles two inches long, each sustaining three or four flowers, of a bluish red on their outside, but white within.—Native of the East Indies. It is propagated by budding or inarching it upon the common White Jasmine, on which it takes very well, and becomes hardier than those which are upon their own stocks. But the plants are seldom raised in England, being brought annually from Italy in great numbers. We shall therefore proceed to detail the management of such plants as are usually brought into England. They are generally tied up in small bunches containing four plants, with their roots wrapped in moss to prevent them from drying, which, when the ship has a long passage, will often occasion them to put out long shoots from their roots, and which shoots must always be taken off before they are planted, otherwise they will exhaust the whole nourishment of the plant, and destroy the graft. In choosing these plants, observe carefully if their grafts be alive and in good health; for if they are brown and shrunk, they will not push out, so that there will be only the stock left, which is of the common sort. When you receive them, clear the roots of the moss, and take off all the decayed branches: place the roots in a pot or tub of water, which should be set in the green-house, or some other room, where it may be screened from the cold; in this situation they may continue two days, after which prune off all the dry roots, and cut down the branches within four inches of the place where they were grafted, planting them in pots filled with fresh light earth; then plunge the pots into a moderate hot-bed of tanner's bark, observing to water and shade them as the heat of the season may require. In about a month or six weeks after, they will begin to shoot, when you must carefully rub off all such as are produced from the stock below the graft; and admit a great share of air, by raising the glasses in the heat of the day. As the shoots extend, they should be topped, to strengthen them, and by degrees should be hardened to endure the open air, into which they should be removed in the beginning of June, but must have a warm situation the first summer, for they will not make much progress if greatly exposed to the wind, being rendered somewhat tender by the hot-bed. If the summer prove warm, and the trees have succeeded well, they will produce some flowers in the autumn following, though they will be few in number, and not near so strong as they will be in the succeeding year, when the trees have acquired better roots. These plants are commonly preserved in green-houses with oranges, myrtles, &c. and during the winter season will require to be frequently watered, which should be sparingly performed, especially in cold weather. In April their shoots should be shortened down to four eyes, and all the weak branches cut off; and if you have the conveniency of a glass stove or a deep frame to place the pots in at that season, it will be of great service in forwarding the flowering

of the plants. They ought not, however, to be too much forced; and as soon as they have made shoots three or four inches long, the glasses should be opened in the day-time, that the plants may by degrees be inured to the open air, into which they may be removed by the latter end of May, or the beginning of June, otherwise their flowers will not be so fair, nor continue so long. If the autumn prove favourable, they will sometimes continue to produce fresh flowers until November, and will sometimes continue flowering much later when they are strong. In mild weather they must have a great share of air, otherwise they will grow mouldy, and decay. Although most people preserve these plants in green-houses, yet they will endure the cold of our ordinary winters in the open air, when planted against a warm wall, and covered with mats in frosty weather; they will also produce ten times as many flowers in one season as those kept in pots; and the flowers will also be much larger. They ought not, however, to be planted abroad till they have acquired strength; so that it will be necessary to keep them in pots three or four years, to shelter them from the severities of winter; and when they are planted against a wall, which should be in May, that they may take good root in the ground before the succeeding winter, you must turn them out of the pots, preserving the earth to their roots, and having made holes in the border where they are to be planted, place them therein with their stems close to the wall; then fill up the holes round their roots with good fresh rich earth, and give them some water, to settle the ground about them, nailing up their shoots to the wall, and shortening such of them as are very long, that they may push out new shoots below to furnish the wall, continuing to nail up all the shoots as they are produced. In the middle or towards the latter end of July they will begin to flower, and continue to produce new flowers until the frost prevents them; which, when you observe, carefully cut off all the tops of such shoots as have buds formed upon them, as also those which have the remains of faded flowers left: for if these are suffered to remain on, they will soon grow mouldy, especially when the trees are covered, and thereby infect many of the tender branches, and greatly injure the trees. Towards the middle of November, if the weather prove cool and the nights frosty, begin to cover the trees with mats, which should be nailed pretty closely over them, and done when the trees are perfectly dry, otherwise the wet being lodged upon the branches will cause a mouldiness, which the exclusion of the air will convert into a rot: hence it will be very necessary to take off the mats as soon as the weather will permit, to prevent this, and keep them closely covered at night and in frosty weather; at which time some mulch should be laid upon the surface of the ground about their roots, and some hay-bands fastened about their stems; to which, in very severe weather, a double or treble covering of mats over the trees should be added, by which precautions they may be preserved through the hardest winters. In the spring, take off these coverings by degrees; but take care not to expose them too soon to the open air, as also to guard them against the morning frosts and dry easterly winds, which are so destructive to tender plants in the month of March. The covering should not be wholly removed until the middle of April, when the season is settled; at which time you should prune the trees, cutting out all decayed and weak branches, shortening the strong ones to about two feet long, which will cause them to shoot strong and produce many flowers.—There is a variety of this with semi-double flowers, which is only to be found in some curious gardens, though it is common in Italy, from whence it is sometimes brought over amongst the single: that with flowers having only two rows of leaves, are rather cultivated for curiosity

than for any extraordinary beauty. It may be propagated by budding it upon the Common White Jasmine, as has been directed for the single, and must be treated in the same manner.

15. *Jasminum Nervosum*. Leaves ovate, three-nerved; stem shrubby, long, climbing, round, even; flowers pure white, scentless.—Native of the hedges of Cochinchina.

16. *Jasminum Trinerve*. Leaves opposite, simple, ovate, attenuated, three-nerved; peduncles axillary, one-flowered; corolla an inch long, smooth, with lanceolate segments.—Native of Java.

17. *Jasminum Scandens*. Leaves opposite, simple, ovate, oblong, attenuated; panicles brachiate; calicine segments bristle-shaped, reflex; peduncles short; pedicels very short.—Native of Bengal, climbing to the tops of trees.

Jatropha; a genus of the class Monœcia, order Monadelphia.—GENERIC CHARACTER. *Male Flowers*. *Calix*: perianth scarcely manifest. *Corolla*: one-petalled, funnel-form; tube very short; border five-parted; divisions roundish, spreading, convex, concave beneath. *Stamina*: filamenta ten, awl shaped, approximated in the middle, the five alternate ones shorter, upright, shorter than the corolla; antheræ roundish, versatile. *Pistil*: a weak rudiment, latent in the bottom of the flower. *Female Flowers* in the same umbel with the males. *Calix*: none. *Corolla*: five-petalled, rosaceous. *Pistil*: germen roundish, three-furrowed; styles three, bifid; stigmas simple. *Pericarp*: capsule roundish, trilocular, three-celled; cells bivalved. *Seeds*: solitary, roundish.—*Observe*. The twelfth species has nine or ten upright stamina, of which the three interior are longer than the rest, to which there are as many bristles corresponding, each placed on each of these filamenta near the base. Some species in the male flowers have a five-cleft calix, and a five-petalled corolla. **ESSENTIAL CHARACTER.** *Male*. *Calix*: none. *Corolla*: one-petalled, funnel-form. *Stamina*: ten, alternately longer and shorter. *Female*. *Calix*: none. *Corolla*: five-petalled, spreading; styles three, bifid. *Capsule*: three-celled. *Seed*: one.—The species are,

1. *Jatropha Gossypifolia*; *Cotton-leaved Physic Nut*, or *Wild Cassava*. Leaves five-parted; lobes ovate, entire, ciliate; bristles glandular, branched on the petioles; stem from two to three feet high, herbaceous, branched, smooth; common peduncle terminating, partial cymed, bifid; male flowers very copious, females solitary, in the forks of the peduncles; corolla deeply five-parted, dark purple.—Native of the West India Islands, and very common all over Jamaica, where the soil is dry and gravelly, and the situation warm. It grows most luxuriantly about houses where the ground is warmed with dung, and rises in such places to the height of three feet and a half, or more. It is very beneficial in every plantation where they keep much poultry, which are very fond of the seeds. A decoction of the leaves is sometimes used in the dry belly-ache, and hence the plant has been called *Belly-ache Weed*. Brown names it Wild Cassava or Casadar. It is cultivated for food, and propagated by cutting the stalks into lengths of seven or eight inches, which when planted put out roots.

2. *Jatropha Glaucæ*; *Glaucous-leaved Physic Nut*. Calicled: leaves five-cleft and three-cleft, serrate-toothed; petioles naked; stipules palmate; stem herbaceous, erect, a foot high, pubescent; peduncles towards the top, opposite to the leaves, three inches long, the height of the stem. It is distinguished from the preceding at first sight by its glaucous hue.—Native of Arabia and the East Indies. This, and many other sorts, are easily propagated by seeds, which should be sown on a good hot-bed in the spring; and when the plants

are fit to remove, they should be each transplanted into a small pot filled with light earth, and then plunged into a fresh hot-bed of tanner's bark, carefully shading them till they have taken fresh root; afterwards they must be treated in the same manner as other tender plants from hot countries, admitting fresh air to them daily, in proportion to the warmth of the season; but as many of the sorts have succulent stalks, some of which have a milky juice, they must have but little water, being soon destroyed by wet.

3. *Jatropha Spinosa*; *Prickly-stalked Physic Nut*. Calicled: leaves three-parted; lobes angular upwards, and quite entire; stem shrubby, prickly; corolla five-petalled.—For its propagation and culture, see the preceding species.

4. *Jatropha Variegata*; *Variegated Physic Nut*. Calicled: leaves lanceolate, quite entire; corymbs axillary, shorter than the leaf; corolla five-petalled; petals oblong; antheræ eight.—For its propagation and culture, see the second species.

5. *Jatropha Glandulosa*; *Glandular Physic Nut*. Calicled: leaves five-lobed, villose; lobes toothletted, glandular; stem shrubby, without stipules. This and the preceding species, though they are furnished with a calix, are distinct from the genus *Croton*, the flowers in that being in spikes.—For its propagation, &c. see the second species.

6. *Jatropha Moluccana*. Leaves ovate, quite entire, somewhat toothed. This is a tree, with alternate, ovate, or ovate-cordate leaves, with some scarcely-conspicuous angles, or one or two teeth; corymb terminating, variously dichotomous. Swartz says, that it ought to constitute a distinct genus.—Native of the Molucca Islands, and of Ceylon. For its propagation and culture, see the second species.

7. *Jatropha Divaricata*. Leaves ovate, acuminate, entire, very smooth; racemes divaricating.—Native of Jamaica. For its propagation &c. see the second species.

8. *Jatropha Curcus*; *Angular-leaved Physic Nut*. Leaves cordate, angular; stem a fathom in height, sometimes seven or eight feet, but rarely more; flowers in terminating cymes; peduncles alternate, upright, many-flowered; flowers almost aggregate, on very short pedicels; corolla five-parted to the base, pale yellow.—Native of South America, and the islands in the West Indies. Brown says it is very common in all the sugar colonies, and is frequently cultivated in inclosures, but dies after a few years. The leaves are much used in resolute baths and fomentations, and the seeds sometimes as a purgative, but they operate violently, and are on that account now but little used. Gærtner suggests, that it was first observed by Boyle, that the fruit might be eaten with safety. For the propagation and culture, see the second species.

9. *Jatropha Multifida*; *French Physic Nut*. Leaves many-parted, even; stipules bristle-shaped, multifid. It grows to the height of five, six, or seven feet, with a very smooth suffrutescent stem, and spreading branches: peduncles terminating, very long, round, thick, very smooth, subdivided; flowers, small, red.—It is now very common in most of the islands in the West Indies, but was first introduced from the continent into the French Islands, and is therefore called French Physic Nut, in the British Islands. It is much cultivated in Jamaica, and forms no small ornament in their flower gardens with its large bunches of beautiful red flowers. The whole plant distils a tenacious watery liquor. The seeds are purgative, but so violent in their operation, that they are now rarely administered, although it was formerly almost the only purgative medicine used among the Spaniards. It flowers from June till August. For its propagation and culture, see the second species.

10. *Jatropha Manihot*; *Eatable-rooted Physic Nut*, or *Cassava*. Leaves palmate; lobes lanceolate, quite entire,

even; root tough, branched, woody, the slender collateral fibres of which swell into those fleshy conic masses, for which the plant is cultivated; and rises by a slender woody knotted stalk, to the height of four, five, or six feet, and sometimes more. The flowers are produced in umbels at the top of the stalks. This plant, which formerly supplied the greatest part of the sustenance of the native Indians, is now raised in most parts of America, and generally considered as a very beneficial vegetable, yielding an agreeable wholesome food, which, with its easy growth, and hardy nature, afford it an universal recommendation. It grows to perfection in about eight months, but the roots will remain a considerable time in the ground uninjured. They are generally dug up as occasion requires, and prepared for use in the following manner: first well washed and scraped, then rubbed to a pulpy farina on iron graters, put into linen or palmetto bags, and placed in a convenient press until the juice is entirely extracted. The farina is then taken out, and spread in the sun for some time, pounded in large wooden mortars, run through coarse sieves, and afterwards baked on convenient irons. These are placed over proper fires, and when hot bestrewed with the sifted meal to whatever size or thickness people please to have the cakes made: this agglutinates as it heats, grows gradually harder, and when thoroughly baked is a wholesome well tasted bread. *Tapioca* is also prepared from this root. What is expressed from the farina is frequently preserved and employed in many economic uses: in boiling it throws up a thick viscid scum, which is always thrown away, and the remaining fluid is sometimes diluted and kept for common drink, and is thought very much to resemble whey in that state. Some use it in sauce for fish and many other sorts of food, as it was used by the native Indians long before Europeans had landed in those parts of the world. The juice of the root is sweetish, but more or less of a deleterious nature, both in a fresh and a putrid state, though it hardly retains any thing of this quality while in a state of fermentation. The milky juice swallowed, or the root eaten without preparation, brings on convulsions, and occasions violent retching and purging: it acts only on the nervous system, and produces no inflammation in the stomach, which, when poisoned by it, appears both in man and other animals to be contracted one half. However violent the rough juice may be found immediately after it is expressed, it is certain that swine eat the roots daily without any detriment; and a little mint-water and salt of worm-wood will remove the most violent symptoms that arise on taking it, and prevent all bad consequences, even in the human species, if but speedily administered. The farina, while yet impregnated with the juice, makes an excellent salve, which seldom fails to cleanse and heal the most desperate sores: where these are very foul, or the parts too much relaxed, it is sometimes mixed with a few pounded tobacco leaves; and has been often found effectual where common ointments have not had the least force. In Madagascar, Cassava is the ordinary food of the Blacks; and the French call it, *Madagascar Bread*. In the West Indies it is called *Cassava*, *Cassada*, or *Cassadar*; in Brazil, *Mandihoca*, *Manuba*; whence we have the name *Manihot*; and in French, *Manihot*, *Magnoc*, *Manioc*, *Manioque*; in Portuguese *Yuca* or *Mandioca*; in Dutch, *Manioc*; and in German, *Manihot*, *Maniok*. The Caribes call it *Juka*, which name is adopted by the Germans and the Spaniards, who call it *Yucca de Cassabe*. At Rio Janeiro they call it the *Flour* or *Meal of the Cassava root*, or *Farinha de Pao*, *Wood Flour*, and not *Powder of Post*, as it has been absurdly translated.—It flowers in July and August. The Cassava root thrives best in the West Indies in a free mixed soil, is propagated by the bud or gem, and is generally cultivated in the

following manner. The ground is first cleared, and hoed up into shallow holes of about ten or twelve inches square, and seldom above three or four inches in depth. When they intend to plant, they provide a sufficient number of full-grown stems, and cut them into junks of about six or seven inches long, as far as they find them tough and woody; and well furnished with prominent well-grown hardy buds: of these they lay one or two in every hole, and cover them over with mould from the adjoining bank; but care must be taken to keep the ground clean till the plants rise to a sufficient height to cover the mould, and to prevent the growth of all weaker weeds.

11. *Jatropha Janipha*. Leaves palmate; lobes quite entire, the middle ones on both sides lobed with a sinus. This is an upright shrub, smooth all over, abounding in an aqueous juice, that is somewhat clammy, and has the smell of walnut leaves. Roots very tuberous, like those of *Asphodel*, in bundles; racemes loose, bearing a few female flowers below many males; corolla yellowish and brownish green. In close woods it frequently rises with a weak, unbranched, rod-like stem, to the height of twenty feet, and it retains this habit in the European stoves.—Native of South America, common about Carthage, flowering almost the whole year; also of China, where, Loureiro says, it is used not raw but boiled, as a resolutive, like the preceding. For its propagation and culture, see the second species.

12. *Jatropha Urens*; *Stinging Physic Nut*. Leaves palmate, toothed, prickly; root thick, swelling, fleshy, from which arises an herbaceous stalk as thick as a man's thumb, four or five feet high, dividing into several branches, closely armed with long brown spines; flowers produced in umbels at the top of the branches, standing upon long naked peduncles. They are of a pure white colour. The nerves are armed with stinging spines. It flowers from May to July, and is a native of Brasil. There is a variety with leaves divided like the common Wolf's-bane.

13. *Jatropha Herbacea*. Prickly: leaves three-lobed; stem herbaceous. The whole plant is closely armed with long stinging bristly spines. The flowers grow in an umbel at the ends of the branches; they are small, of a dirty white colour.—Native of La Vera Cruz. It is an annual plant: if the seeds be sown early in the spring, and the plants are brought forward, they will perfect their seeds the same year; but the other sorts are perennial, and do not flower till the second or third year; therefore the plants should be plunged into the tan-bed in the stove, where they should constantly remain, giving them a large share of air in warm weather; but in winter they must be tenderly treated, and must then have very little water. With this management the plants will continue several years, and produce their flowers, and frequently perfect their seeds in England.

14. *Jatropha Elastica*; *Caoutchouc* or *Elastic Gum Tree*. Leaves ternate, elliptic, quite entire, hoary underneath, on long petioles. This tree is described as very lofty and straight, and quite naked up to the head, which is very small; the trunk of the largest is only about two feet in diameter; the fruit is triangular, inclosing three seeds: these seeds or kernels, peeled and boiled in water, yield a thick oil, which the Indians use as butter with their food; the wood of the tree is light, and fit for masts.—It is a native of Guiana; of Quito, and Brasil, particularly in Para, where it is called *Massaradub*. The Indians, by an incision in the bark, extract a viscid white substance, like that which issues from the fig-tree; they receive it into earthen moulds, to make rings, bracelets, girdles, syringes, hats, boots, flambeaux, figures of animals, &c. The Abbe Rochon says, that the

inhabitants of Madagascar also made flambeaux of it, which burn without wicks, and afford them a very good light when they go out to fish in the night time: and observes that it has been useful for bandages in surgery, and for coating over the silk for balloons, &c. so as to render it impervious to air or water. It has the extensibility of leather, with very considerable elasticity; spirit of wine makes no impression on it, but it dissolves in ether and linseed oil, or in nut oil digested gently in a sand bath; there are also other fat and oily substances which affect it very sensibly. The Chinese have been long acquainted with the art of dissolving it, and of giving it various colours; but perhaps the purpose to which it has been most universally applied, is that of obliterating pencil lines, for the reader will by this time suspect it to be nothing less than our famous India Rubber, to which artists and accountants are under such great obligations; though all the writers who have treated upon this species, have thought it beneath their dignity to make such a remark. It was first found by Mons. Condamine, in 1745, upon the banks of the river of Amazons, and is very common in Quito, where it is called *Hheve*.

Iberis; a genus of the class Tetradymania, order Siliculosa.—GENERIC CHARACTER. *Calix*: perianth four-leaved; leaflets obovate, concave, spreading, small, equal, deciduous. *Corolla*: four-petalled, unequal; petals obovate, obtuse, spreading; claws oblong, upright: of these the two exterior petals are far larger, and equal to each other; the two interior very small, reflex. *Stamina*: filamenta six, awl-shaped, upright, of which the two lateral ones are shorter; antheræ roundish. *Pistil*: germen roundish, compressed; style simple, short; stigma obtuse. *Pericarp*: silicle upright, suborbiculate, compressed, emarginate, surrounded by a sharp edge, two-celled; partition lanceolate; valves navicular, compressed, carinated. *Seeds*: a few, subovate. *Observe*. The sixth species has nearly equal flowers, and a subquadrangular silicle: the silicle is not emarginate in the seventh species. *Is the partition bipartite in all the species?* ESSENTIAL CHARACTER. *Corolla*: irregular, with the outer petals larger; silicle emarginate, many-seeded: in some of the species one seed only in each cell.—The species are,

1. *Iberis Semperflorens*; *Broad-leaved Evergreen Candy-tuft*. Frutescent: leaves wedge-shaped, quite entire, blunt. A shrubby plant, seldom rising above a foot high, having many slender branches; flowers produced at the end of the shoots; they are white, and grow in an umbel, continue long in beauty, and being succeeded by others, the plants are rarely destitute of them, from the end of August till the beginning of June, which circumstance makes this a very valuable plant.—Native of Persia and Sicily. It is somewhat tender, and generally sheltered during winter in a green-house, where, being placed among other diminutive plants to the front of the house, it makes a pleasing variety, flowering throughout the winter; but though usually thus treated, in moderate winters it will live in the open air, if it be planted in a warm situation and on a dry soil; and if in very hard frost it be covered either with mats, reeds, straw, or peas-haulm, it may be preserved very well, and these plants which grow in the full ground will thrive better, and produce a greater number of flowers, than those which are kept in pots: but the soil in which these are planted, should not be over-rich nor too wet, for in either of these they will grow too vigorously in summer, which will place them in greater danger of suffering by the frost in winter; but when they grow on a gravelly soil, or among lime rubbish, their shoots being short, strong, and not so replete with moisture,

will better resist the cold. The plant rarely produces seeds in England, and is therefore only propagated by cuttings, which, if planted during the summer months, and shaded from the sun, and duly watered, will be rooted in two months, and may afterwards be either planted in pots, or into the borders where they are designed to stand. The variety with striped leaves not being so hardy as this, must be more tenderly treated in winter, and may also be increased by cuttings.

2. *Iberis Sempervirens*; *Narrow-leaved Evergreen Candy-tuft*. Frutescent: leaves linear, quite entire, acute. It flowers as long as the preceding species, and the leaves continue green throughout the year.—It flowers from April to June, and is a native of the island of Candia, on rocky ground. As this species rarely produces seeds in England, it is increased by slips, which easily take root in summer: the plant may be treated in the same manner as the first sort, and will thrive in the open air.

3. *Iberis Garexiana*. Leaves oblong-lanceolate, acute; stems fruticulose, diffused, flexile, warted; branchlets leafy, upright; root horizontal, with many fibres; stems many, depressed, brown, round, naked, commonly simple; corolla white, the two outer petals double the size of the others. It has no smell; the seed-vessel differs no otherwise from a capsule, than in having deciduous valves, and it has only a single seed in each of the two cells.—Native of Piedmont, about Strop, above Tende, in the high mountains between Briga and Carlin, and above Frabrosa.

4. *Iberis Gibraltaria*; *Gibraltar Candy-tuft*. Frutescent: leaves toothed at the tip; stems many, thick, green, striated, ascending, from a foot to eighteen inches in length, divided into several branches; flowers terminating in corymbs, first white, afterwards pale purple, without scent, the two outer petals broader and longer: the flowers bear some resemblance to those of the eighth species, but when they blow in perfection, they are usually twice as large; hence they are highly ornamental to the green-house early in the spring, at which time they appear. It is nearly allied to the first species, but is less shrubby and woody, the leaves are toothed towards the end, and the flowers are in larger corymbs.—Native of Spain. It is easily raised from cuttings, and may be kept through the winter in a common hot-bed frame; in mild winters it will stand abroad, especially if sheltered among rock-work: moisture often destroys it in the winter season; the moisture ought therefore to be dissipated by gentle heat.

5. *Iberis Saxatilis*; *Rock Candy-tuft*. Suffrutescent: leaves lanceolate-linear, fleshy, acute, quite entire, ciliate; root woody, hard, twisted, and large; stems diffused, numerous, branched at the base, scarred with fallen branches and leaves, three or four inches high; the stems and branches are almost naked at top, and terminate in a corymb of white or purple flowers: in the progress of the inflorescence the corymb becomes a raceme.—Native of the South of France and Italy. This and the two following species are propagated by seeds sown on a shady border in autumn: when the plants are strong enough to remove, transplant them into a shady border, where they are to remain, and they will require no other care but to keep them clean from weeds. The flowers of this plant have a pleasant smell.

6. *Iberis Rotundifolia*; *Round-leaved Candy-tuft*. Herbaceous: leaves ovate; stem leaves embracing, even, juicy; stems naked, slender, creeping, branched; flowers in racemes on spreading peduncles; calix reddish; petals purple, with the border entire, blunt, oval; seed smooth. It flowers from May to July; perennial.—Native of Switzerland,

Carniola, the south of France, Italy, and Silesia. See the fifth species.

7. *Iberis Cepeæfolia*. Herbaceous: leaves ovate; stem-leaves sessile, even, juicy; root long, round, slender, fungous, branched, creeping obliquely, reddish violet-coloured on the outside; stems several, scarcely half a span in height; petals obovate, oblong, entire, equal, lilac-coloured; flowers sweet-smelling like the preceding: they appear in May.—Native of Carinthia. See the fifth species.

8. *Iberis Umbellata*; *Purple Candy-tuft*. Herbaceous: leaves lanceolate, acuminate, the lower serrate, the upper quite entire; stem upright, leafy, half a foot, or a span to a foot in height; root annual, white, oblong, fusiform; flowers in a hemispherical corymb, on peduncles half an inch in length; the usual colour is a pale purple, but there is one variety with bright purple, and another with white flowers; the flowers appear in June and July, and may be continued in succession till autumn.—Native of the south of Europe. This, with the ninth and eleventh species, are sown in small patches upon the borders of the flower-garden; and, by sowing them at three or four different times, there may be a succession of them in flower till autumn; when they are grown up, they should be thinned, that they may put out side branches, flower stronger, and continue longer in beauty. This plant was formerly sown for edgings; for which it is, like all other annuals, extremely unfit.

9. *Iberis Amara*; *White Candy-tuft*. Herbaceous: leaves lanceolate, acute, somewhat toothed; flowers in racemes. Linneus observes, that this resembles the preceding very much, being only smaller; it differs however in many other respects: stem seven or eight inches high, pubescent, somewhat rugged, branched; flowers white, in a terminating spike-like raceme, or rather in a corymb, lengthened into a raceme as the inflorescence advances.—Native of Switzerland, Germany, Austria, south of France, and England, where it is found about Henley, Nettlebed, and Mungewell, in Oxfordshire, and on Wallingford common, in Berkshire. See the preceding species.

10. *Iberis Linifolia*; *Flax-leaved Candy-tuft*. Herbaceous: leaves linear, quite entire; stem-leaves serrate; stem panicled; corymbs hemispherical; root simple, white, twisted, having few fibres; stem herbaceous, straight, slender, branched at top; branches mostly bifid; flowers in corymbs, the outer ones peduncled, with the two outer petals larger, the colour is purple, and they appear in July.—It is an annual plant, and a native of Spain, Portugal, and Provence. It may be increased by cuttings, in the same manner as the first species: some of the plants may be set on a warm border, in a dry soil; leaving two or three in pots, to be sheltered under a frame in winter, in case of a severe frost.

11. *Iberis Odorata*; *Sweet-scented Candy-tuft*. Herbaceous: leaves linear, widening at top, and serrate. This seldom grows so large as the Purple Candy-tuft, and the flowers are much smaller, but have an agreeable odour: they are in close corymbs, and of a snowy whiteness.—Native of the mountains near Geneva. See the eighth species.

12. *Iberis Arabica*. Herbaceous: leaves ovate, smooth, veinless, quite entire; silicles two-lobed at the base and tip.—Native of Arabia and Cappadocia.

13. *Iberis Nudicaulis*; *Naked-stalked Candy-tuft*, or *Rock-cress*. Herbaceous: leaves sinuate; stem naked, simple; root-leaves spread on the ground in a circle, petioled; flowers in a terminating spike-like raceme, small, white, and scentless, on peduncles half an inch long, and spreading wide.—Native of most parts of Europe, in dry and barren

soils. It is found on Hounslow-heath, Putney, and Barnes commons, and near Hampton-court and Richmond; at Blackheath by the road from Greenwich to Lewisham; at Ilford, in Essex; near Gamlingay, in Cambridgeshire; Bungay, in Suffolk, and near Norwich; near Pensham, in Worcestershire; at Harmer-hill, near Salop; at Nottingham-park; at Little Creaton, in Northamptonshire; between Corby Castle and Carlisle, and in some parts of Scotland. This diminutive plant is rarely admitted into gardens; the seeds may be sown in autumn where the plants are designed to remain, and require no other care but to keep them clean from weeds.

14. *Iberis Pinnata*; *Winged Candy-tuft*. Herbaceous: leaves pinnatifid; stem about a foot and a half in height, commonly simple, but sometimes with a branch or two; flowers in a corymb, clear white, seldom purple.—It flowers from July to August, and is a native of the south of Europe.

Ice House; a building sunk in the ground, to preserve ice for the use of a family in the summer season. In the choice of a situation for an ice-house, the principal regard should be that of a dry spot of ground, for wherever there is moisture the ice will melt; therefore in all strong lands, which retain the wet, there cannot be too much care taken to make drains all round the building to carry off all moisture; which, when lodged near the building, will produce a damp that will always be prejudicial to the preservation of the ice. The next consideration must be, to have the place so elevated, that there may be descent enough to carry off whatever wet may fall near the building, or from the ice melting; also, that the place be as much exposed to the sun and air as possible, and not placed under the drip or in the shade of trees, as has been so often practised, under a false notion, that, if it should be exposed to the sun, the ice will melt away in summer; which never can be the case where there is sufficient care taken to exclude the outward air, (which must always be attended to in the building of these houses,) for the heat of the sun can never penetrate through the double arches of the building, so as to add any warmth to the air: but when it is entirely open to the sun and wind, all damps and vapours will be thereby removed from about the building, which cannot be kept too free from moist vapours. The form of the house may be adapted to the fancy of the owner, but the well into which the ice is to be put should be circular, and the diameter and depth proportioned to the quantity of ice it is proposed to contain. It is best to take care that it be amply capacious, so as to hold an abundance; for, when the house is well built, it will keep the ice for two or three years, which will secure this advantage, that the stock will hold out during a mild winter whenever it may occur. If the quantity required is not great, a well of six feet diameter and eight feet depth will be large enough; but for a large consumption it should not be less than nine or ten feet in diameter, and as many deep. Where the situation is either dry chalk, gravel, or sand, the pit may be entirely below the surface of the ground; but in strong loam, clay, or moist ground, it will be better to raise it so high above the surface as to obviate the approach of wet. At the bottom of the well, there should be a space left two feet deep, to receive any moisture which may drain from the ice, from which a small underground drain should be laid to carry off the water. Over this should be placed a strong grate of wood, to let the moisture descend. The sides of the well must be walled up with brick or stone, at least two feet thick; but the thicker the better, for the less danger there will be of the ice being affected by any external cause. When the well is brought

within three feet of the surface, there must be another outer wall or arch begun, and carried up to the height of the top of the intended arch of the well; and if there be a second arch turned over from this well, it will add to the goodness of the house, if the person building be willing to suffer the expense; but if not, then the plate into which the roof is to be framed must be laid on this outer wall, which should be carried high enough above the inner arch to admit of a doorway in, to get out the ice. If the building is to be covered with slates or tiles, there should be a thickness of reeds laid under, to keep out the sun and external air: if these reeds be laid two feet thick, and plastered over with lime and hair, there will be no danger of the heat getting through it. The external wall need not be circular only; it may be either square, hexangular, or octangular, and, where it stands much in sight, may be contrived so as to form a good object. The building being finished, should have time to dry before the ice is put into it, for the damp of green walls frequently melts the ice. Upon the wooden grate, at the bottom of the well, some small faggots should be laid, and if a layer of reeds be smoothly placed upon these, it will be better for the ice to lie upon than the straw, which is commonly used. In choosing ice, observe, the thinner it is, the better it may be broken to powder, and the more easily it will unite when put into the well. Care must be taken to ram it close, and, by laying straw all round the wall, to allow a vacancy of about two inches to drain off the moisture that may be occasioned by the melting of the ice on the top, which, if not drawn off, will melt the ice downwards. A little saltpetre mixed with the ice, at every ten inches or a foot thickness, when it is put into the well, will cause it to unite more closely into a solid mass: and there must be a crow, or other iron instrument, always in readiness to break it up, taking out no more at each time than is immediately wanted.

Ice-Plant. See *Mesembryanthemum*.

Jerusalem Artichoke. See *Helianthus*.

Jerusalem Cowslip. See *Pulmonaria*.

Jerusalem Sage. See *Phlomis*.

Jesuit's Bark. See *Cinchona*.

Jew's Mallow. See *Corchorus*.

Ignatia; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, short, bell-shaped, five-toothed; teeth upright, ovate, obtuse. *Corolla*: one-petalled, funnel-form; tube filiform, of a span length, smooth, upright; border flat, five-parted; divisions oblong, obtuse, perfectly entire. *Stamina*: filamenta five, inserted into the receptacle, length of the tube, thread-shaped, very smooth; antheræ five, converging into an oblong column, which is five-cornered, sharp, and rough. *Pistil*: germen very small, ovate, very smooth; style filiform, length of the stamina; stigma slender, two-parted; divisions awl-shaped. *Pericarp*: berry pear-shaped, large, one-celled, with a thick woody bark. *Seeds*: several, covered with a thin cuticle, solid, horny, very hard; the lateral ones irregularly tetragonal, with the inner sides flat, the outward gibbose, the interior oblique; the central one hexagonal, with flat sides. **ESSENTIAL CHARACTER.** *Calix*: five-toothed. *Corolla*: funnel-form, very long. *Fruit*: one-celled, many-seeded.—The species are,

1. *Ignatia Amara*. Leaves ovate, acute; stem scandent; peduncles axillary, four-flowered or thereabouts. This is a branching tree; the branches long, round, very smooth, climbing; flowers very long, nodding, white, in small panicles; fruit ovate, with a very smooth dry rind.—Native of the East Indies and Philippine Islands, whence it has been transported to Cochinchina, and other countries, for cultivation. The

seeds under the name of St. Ignatius's Beans, are much used in the East Indies, and are reputed to be tonic, diaphoretic, emmenagogue, and anthelmintic. They are used in the pituitary apoplexy, colic, cardialgia, intermittent fevers, suppression of the menses, and bites of venomous animals. The dose is from six to twelve grains, reduced to powder, either in wine or water. They never produce any bad effect, although they do not always operate, but are often productive of great relief; too large a dose will bring on vertigo and convulsions, which may be easily removed by drinking freely of lemonade. The younger Linneus erroneously asserts, that the seeds are as poisonous to animals as those of the *Nux Vomica*; for a whole nut, weighing a drachm, has been given to oxen, buffaloes, horses, and swine, without any ill effect. Neither is it true that these seeds are never spoiled by keeping or by worms, for they are often found with holes eaten in them, in moist places, in the East Indies.

2. *Ignatia Longiflora*. Leaves oblong, waving, acuminate; peduncles terminating, six-flowered, or thereabouts. This is a branching shrub, five or six feet high, with a smooth green bark, and a white hard wood; flowers terminating, about six in number, on a common peduncle; corolla white, with a tube a foot in length. It flowers in November, fruits in January, and is a native of Guiana on the banks of large rivers. The Caribbee name is *Aymara Posoqueri*.

Ilex; according to Linneus, a genus of the class Tetrandria, order Tetragynia; according to Hudson, class Polygamia, order Diœcia.—**GENERIC CHARACTER.** *Calix*: perianth four-toothed, very small, permanent. *Corolla*: one-petalled, four-parted, wheel-shaped; divisions roundish, spreading, rather large, with cohering claws. *Stamina*: filamenta four, awl-shaped, shorter than the corolla; antheræ small. *Pistil*: germen roundish; style none; stigmas four, obtuse. *Pericarp*: berry roundish, four-celled. *Seed*: solitary, bony, oblong, obtuse, gibbose on one side, cornered on the other. **ESSENTIAL CHARACTER.** *Calix*: four-toothed. *Corolla*: wheel-shaped; style none. *Berry* four-seeded.

—The species are,

1. *Ilex Aquifolium*; *Common Holly*. Leaves ovate, acute, spiny, shining, waved; flowers axillary, subumbelled. It rises from twenty to thirty feet high, and sometimes more, for Bradley mentions a tree sixty feet high; but its ordinary height is not above twenty-five feet. The trunk is covered with a grayish smooth bark; and those trees which are not lopped or browsed by cattle, are commonly furnished with branches for the greatest part of their length, and form a sort of cone. Flowers in clusters from the base of the petioles, form a sort of scale upon the branch, upon very short peduncles, each sustaining five, six, or more flowers, which appear in May; corolla of a dirty white. Mr. Miller says, "In some plants I have observed the flowers were wholly male, and produced no berries; in others female and hermaphrodite; but I found all three upon some old trees growing in Windsor Forest." The late Sir William Watson also made an observation of the same sort. Gerarde remarked hermaphrodite flowers with five petals on one tree, and male flowers with a four-parted petal and an abortive germen on another tree. Professor Martin also says, that in the trees which he observed, the petals were four-parted; and Dr. Withering remarks, that he found the Holly in flower so late as the second week in June, and then all the flowers had four stamina and four pistilla; which Haller confirms. Mr. Hudson however describes a five-toothed calix and five-parted corolla in the hermaphrodite, with five stamina, five stigmata, and a four-seeded berry; in the male, a four-toothed calix, a four-parted corolla, and four stamina: but whether this be

from his own observation, or only founded on Gerarde's, we are at a loss to know. He has removed the Holly from the class where Linneus and others have placed it, into that of Polygamia order, where it certainly ought to be found, according to the above observations. But it is judiciously remarked by Dr. Stokes, that "before it be removed to another class, it is proper to show that the majority of the other species are liable to similar sexual variations." This very beautiful tree deserves a place in all plantations of evergreens and shrubs, where its shining leaves and scarlet berries make a fine variety; and, if a few of the best variegated sorts be properly intermixed, they will enliven the scene. The Holly makes an impenetrable fence, and bears cropping well; nor is its verdure, or the beauty of its scarlet berries, ever observed to suffer from the severest of our winters; it would therefore form a better fence than the Hawthorn, were it not for the shortness of its growth whilst young, and the difficulty of transplanting it when grown to a moderate size; but if it once take well, the hedge may be rendered so close and thick, as to exclude all sorts of animals. Evelyn's impregnable Holly hedge, four hundred feet in length, nine feet high, and five thick, has been much celebrated by himself, Mr. Ray, and others. Mr. Miller says, that a Holly hedge should never be clipped with shears, because, when the leaves are cut through the middle, they are rendered unsightly, and should therefore be cut with a knife, close to a leaf; and although by this method, it is not shorn so even, it will have a much better appearance. This may be done to ornament a garden hedge, but it is obviously impracticable upon a large scale. The clipping a holly hedge should not be done later than July. It does best in cold stony lands; prospers on gravel, over chalk; and refuses not, says Mr. Boucher, the poorest, hot, sandy, gravelly, and rocky ground, nor the coldest clay; on which last, however, it has been observed to advance with a most discouraging slowness. Mr. Marshall relates, "that in the Wolds of Yorkshire, he has seen the Holly raised, by the practice of a man who paid great attention to the business of hedge-planting, with an unusual rapidity and certainty; this man's secret would be of inestimable value to the public, and perhaps our intelligent readers in that part of the kingdom, may think it worth their while to endeavour to discover and make it known." Forty or fifty varieties, depending on the variegations of the leaves or thorns, and the colour of the berries, derived from this one species, are raised by the nursery gardeners for sale, and were formerly in very great esteem, but are less regarded, since the old taste of filling gardens with shorn evergreens, has been laid aside; a few, however, of the most lively varieties, would have a good effect in the plantations during the winter season, if properly disposed.—The following are the most beautiful varieties: Painted Lady; British; Bradley's-best; Phyllis, or Cream; Milkmaid; Pricet's-best; Cheyne's; Glory of the West; Broderick's; Partridge's; Herefordshire white; Blind's Cream; Long-staff's; Eales's; Gold-edged, and Silver-edged Hedge-hog Holly; Chohole; Box-leaved Green; Chimney-sweeper; Glory of the East; Wife's; Gray's; Common-blotched; Yellow-blotched Hedge-hog; Blotched Yellow-berried; Mason's; Copper-coloured; Sir Thomas Frankland's Britain; Whitmill's; Bradley's Long-leaved; Bradley's Yellow; Bridgman's; Wells's; Glass's; Bagshot; Brownrig's; Lanton; Aslet's; The Union; Fuller's Cream; Capel's Mottled; and the White-berried. Of all the varieties above enumerated, the Hedge-hog Holly is the most remarkable. Miller, indeed, will have it to be a distinct species, and says that the leaves are not so long as

those of the common Holly, and have the edges armed with stronger thorns, standing close together, the upper surface set very close with short prickles; as it retains its difference when raised from berries, Mr. Miller insists that it is a distinct species, and informs us that there are two varieties of it, one with variegated leaves, and the other white. It grows naturally in Canada.—The wood of the Holly-tree, says Evelyn, is the whitest of all hard woods, and is used by the inlayers, especially under thin plates of ivory. The millwrights, turners, and engravers, prefer it to any other; it makes the best handles and stocks for tools, flails, riding-rods, and carters' whips, bowls, clivers, and pins for blocks, and is also excellent for door bars and bolts; it is made even into hoes for setting razors, and takes so fine a polish, that it is very suitable for several kinds of furniture. Mr. Miller mentions the floor of a room laid in compartments of this wood, with mahogany, which had a very pretty effect. It is much used with box, yew, and white-thorn, in the Tunbridge ware, and in veneering, and is sometimes also stained black to imitate ebony. Sheep are fed during winter with the croppings; birds eat the berries; and the bark fermented, and afterwards washed from the woody fibres, makes the common *birdlime*. The berries are of a warm carminative nature, and good for relieving the colic; they may be taken to the number of twelve or fourteen at a time; and as they purge, often occasion a considerable evacuation of wind and slime by stool. A decoction of the leaves in milk or ale, produces the same effects, and is serviceable in pains and weakness of the back. A person who was noted for his success in the cure of rheumatic complaints, used no other medicine than a decoction of the young buds or leaves of this tree in water, which, after being strained, was sweetened with coarse sugar, and given to the patient to drink, while warm in bed, to the amount of half a pound weight of the liquid, three or four times a day, till the pain was removed, or at least alleviated; it operated in all cases as a very powerful sudorific; and plenty of small diluting liquors were ordered to be drank during the operation. Culpeper says, "that the dry berries, pounded into powder, will stop fluxes, bloody fluxes, and immoderate menstrual evacuations; and that the bark and leaves are excellent to foment broken bones, or dislocated joints." This tree grows wild in many parts of Europe, North America, Japan, and Cochin-china, and is found in woods and forests in many parts of England, where it is called Hulver and Hulme, as well as Holly: the Germans give it many names, such as *Stechpalme*, *Christdorn*, *Wald-distel*, &c.; the Danes call it *Stikpalme*, *Christtorn*, &c.; the Swedes, *Jernek*, and *Christtorn*; the French, *Le Houx*, *Le Grand Houson*, *L'Agron*, *Grand Pardon*, *Bois Franc*; the Italians, *Agrifoglio*, *Alloro Spinoso*; the Spaniards, *Acebo*, *Agrifolio*; the Portuguese, *Azevinho*, *Agrifolio*, *Aerifolio*, *Aquifolio*; and the Russians, *Wassoscheld*, *Ostrokrof*, and *Padub*. This valuable tree is propagated by seeds, which never come up the first year, but lie in the ground like the haws; the berries therefore should be buried in the ground, in a large pot or tub, one year, and then taken up in the autumn, and sown upon a bed exposed only to the morning sun; the following spring the plants will appear, and must be kept clean from weeds; and if the spring should prove dry, it will be of great service to the plants if they are watered once a week, but in small quantities, for much moisture is very injurious to them when young; in this seed-bed the plants may remain two years, and then should be transplanted in the autumn, into beds at about six inches' distance each way, where they may stand two years longer, during which time they must be

kept constantly clean from weeds; and, if the plants have thriven well, they will be strong enough to transplant where they are intended to remain; for when they are transplanted at that age, there will be less danger of their failing, and they will grow larger than those removed at a later period: if the ground, however, be not ready to receive them at that time, they ought to be transplanted into a nursery, in rows at two feet distance, and one foot asunder in the rows, where they may remain two years longer; and if they are designed for grafting or budding with any of the variegated kinds, that should be performed after the plants have grown one year in this nursery; but the plants so budded or grafted, should remain two years after that in the nursery, that they may make good shoots before they are removed: the best time for removing Hollies, is in the autumn, especially in dry land; but where the soil is cold or moist, they may be transplanted with great safety in the spring. Evelyn declares, that he has raised hedges four feet high in four years from seedlings taken out of the woods; and that the varieties with white berries, and gold and silver leaves, may be raised from seeds sown and planted in a gravelly soil, mixed with store of chalk, and pressed hard down. The stocks will be fit to be grafted or budded at four or five years' growth; the grafting must be done in March, and the budding in July. For sowing, Boucher directs that the berries should hang on the trees till December, or, if they could be defended from birds, till February or March; as soon as they are gathered, throw them into a tub with water, and rub them between your hands till the seeds are divested of their thick glutinous covering; pour off the water, with the light seeds and mucilage, and spread the seeds on a cloth, in a dry airy place, rubbing them often, and giving them a fresh cloth daily, till the seeds are quite dry: if this be done in autumn or winter, mix them with sand, and keep them dry till spring; but if they have been gathered in spring, let them be immediately sown; this may be done any time, during seasonable weather, in March or April.

2. *Ilex Opaca*; *Carolina Holly*. Leaves ovate, acute, spiny, smooth, flat; flowers scattered at the base of the last years' shoots. It flowers in May and June.—Native of Carolina.

3. *Ilex Ferado*; *Thick-leaved Smooth Holly*. Leaves ovate, with a point, unarmed, almost entire. It flowers in April and May.—Native of Madeira.

4. *Ilex Prinoides*; *Deciduous Holly*. Leaves elliptic, lanceolate, acute, deciduous, serrate; serratures without prickles. It flowers in July.—Native of Carolina and Virginia.

5. *Ilex Cassine*; *Dahoon Holly*. Leaves alternate, distant, evergreen, lanceolate, serrate; serratures acuminate: it rises with an upright branching stem to the height of eighteen or twenty feet; the flowers come out in thick clusters, from the sides of the stalks, they are white, shaped like those of the common holly, but smaller; both the female and hermaphrodite flowers are succeeded by small roundish berries, making a fine appearance in winter; but they have not as yet produced any fruit in England. There are two varieties, with broader and narrower leaves, with scarcely any serratures. It is tender while young, and requires protection in the winter till the plants are grown strong and woody, when they may be set in the full ground, in a warm situation, where they will endure the cold of our ordinary winters very well, but must be protected from severe frost, which would destroy them. It is propagated from seeds in the same manner as the common sorts, and the seeds will lie as long in the ground; they should therefore be buried

a year in sand, unless forwarded as above directed; when taken up, they should be sown in pots filled with light earth, and placed under a frame in winter, and in the spring the pots should be plunged into a hot-bed, which will bring up the plants; they must be preserved in the pots while young, and sheltered in winter under a common frame till they have obtained strength, when in the spring they may be turned out of the pots, and planted in the full ground in a warm situation.

6. *Ilex Vomitoria*; *South Sea Tea*, or *Evergreen Cassine*. Leaves alternate, distant, oblong, bluntish, crenate, serrate; serratures without prickles. It rises to the height of ten or twelve feet, sending out branches from the ground upwards, which form themselves into a sort of pyramid; the flowers are produced in close whorls at the joints of the branches, near the footstalks of the leaves, they are white, and are succeeded by red berries, which continue upon the plants most part of the winter, and, being of a bright red colour, makes a fine appearance intermixed with the green leaves; from the berries continuing so long untouched by the numerous birds of their native climate, they are fairly suspected of having a poisonous quality. The leaves of this tree are not so bitter as those of the Cassine, or Cassio-berry bush, especially when green, and are therefore preferred for making an infusion in the manner of tea, which the Indians reckon very wholesome, and is the only physic they use in some parts. At a certain time in the year they come down by droves, from a distance of some hundred miles, to the coast, for the leaves of this tree, which is not known to grow at any considerable distance from the sea; they make a fire on the ground, and, putting a great cauldron of water on it, throw in large quantities of these leaves, and, seating themselves round the fire, from a bowl that holds about a *pint*, begin drinking large draughts, which in a very short time occasions them to vomit easily and freely: thus they continue drinking and vomiting for *several days*, until they have sufficiently evacuated and cleansed their stomachs, and then every one taking a bundle of the tree to carry with him, they all return to their respective habitations. This plant is generally supposed to be the same as that which grows in Paraguay, where those vermin, the Jesuits, raise a great revenue from the leaves.—Native of West Florida, Carolina, and some parts of Virginia. It is propagated by seeds, sown in pots filled with light sandy earth, and plunged into a gentle hot-bed, observing to water them frequently until the plants appear, which is sometimes in five or six weeks' time, but at other times they will remain in the ground until the second year; therefore, if they should not come up in two months, remove the pots into a shady situation, where they may remain till October, being careful to keep them clean from weeds, and now and then, in dry weather, give them a little water; then remove the pots into shelter during the winter, and in March put them upon a fresh hot-bed, to forward the seeds for vegetation; when the plants come up, gradually expose them to the open air, to inure them to the climate, yet they should not be exposed to the open sun at first, but have the morning sun only, placing them for some time where they may be sheltered from cold winds: as they grow slowly, they should be kept in pots four or five years.

7. *Ilex Asiatica*. Leaves broad, lanceolate, blunt, quite entire.—Native of the East Indies.

8. *Ilex Cuneifolia*. Leaves wedge-form, three-cusped.—Native of South America.

9. *Ilex Integra*. Leaves oblong, obtuse, entire; peduncles one-flowered; flowers in a sessile umbel; petioles three-

and mat so much, that they hold it together. On the Maese they grow upwards of four feet high; and in the summer, when they are fully grown, the Dutch cut them, tie them up in bundles, dry them, and work them into baskets.

3. *Juncus Conglomeratus*; *Round-headed Rush*. Culm naked, stiff; head lateral; root perennial, horizontal, close, covered with ovate scales; fibres filiform, very long; head of flowers roundish.—Native of Europe, on moist meadows and heaths.

4. *Juncus Effusus*; *Common Soft Rush*. Culm naked, stiff, smooth; panicle lateral, scattered, close; root-scales opaque; flowers brownish; seeds fulvous. They are sometimes used for making little baskets, and the pith of both makes wicks for watch-lights, and toys. This and the next species both grow on moist, strong, uncultivated lands in most parts of England, and consume the herbage where they are suffered to remain. The best method of destroying them is to fork them up clean by the roots in July, and, after having let them lie a fortnight or three weeks, to put them in heaps, and burn them gently: the ashes will be good manure for the land. But to prevent their growing again, and to make the pasture good, the land should be drained; and then, if the roots be annually drawn up, and the ground kept duly rolled, the rushes may be subdued. They flower in July and August.—Native of Europe, in wet meadows, marshes, &c.

5. *Juncus Tenax*; *Common Hard Rush*. Culm naked, stiff, striated; panicle lateral, thin; root-scales shining; root perennial.—It is common in pastures and by road-sides, in a moist soil, in England, Madeira, and New Zealand. See the preceding species.

6. *Juncus Inflexus*; *Bending Soft Rush*. Culm naked, membranaceous, and curved in at top; panicle lateral; roots tufted; flowers abundant, on many peduncles, issuing from a cleft in the culm. This has often been mistaken for the preceding.—Native of the south of Europe, in clear water, upon a strong soil.

7. *Juncus Filiformis*; *Least Soft Rush*. Culm naked, filiform, nodding; panicle lateral; roots perennial, horizontal, creeping; peduncles mostly simple, bearing one flower, rarely more, triangular, furnished with a few sheath-like scales at their base; seeds small, numerous.—Native of Lapland, Switzerland, Germany, Italy, and Britain, where it has been observed on turf-bogs near Ambleside in Westmoreland; at Windermoor in Cartmel; near Derwentwater in Cumberland; and on Ben Lawers in Scotland.

8. *Juncus Trifidus*; *Three-flowered Rush*. Culm naked; leaves and three flowers terminating; root perennial, woody, striking deep, creeping with blackish fibres, putting forth close tufts of stems and leaves.—Native of Lapland, Denmark, Switzerland, France, Silesia, and Scotland on the summits of the Highland mountains.

9. *Juncus Squarrosus*; *Moss Rush*, or *Goose Corn*. Culm naked; leaves bristle-shaped; heads glomerate, leafless; root perennial. Horses are said to eat it. It indicates a barren soil; and the leaves, lying close to the ground, elude the stroke of the scythe. It flowers in June and July, and is found on moist heathy ground, and turf-bogs, all over Europe.

10. *Juncus Punctorius*. Culm naked, round; leaf round, jointed, mucronate; panicle glomerate; root-leaves none.—Native of the Cape of Good Hope.

** *With leafy Culms.*

11. *Juncus Nodosus*. Leaves knotted, jointed; petals mucronate.—Native of North America.

12. *Juncus Compressus*; *Lesser Jointed Rush*. Culm leafy, decumbent; leaves compressed, knotted, jointed; panicle

compound; root perennial, horizontal, woody, round, fibrose.—Native of meadows and marshes.

13. *Juncus Nemorosus*; *Greater Jointed Rush*. Culm leafy, erect; leaves roundish, knotted-jointed; panicle super-decompound.—Native of moist woods.

14. *Juncus Uliginosus*; *Least Jointed Rush*. Culm leafy; flowers in bundles; bundles proliferous; leaves bristle-shaped, jointed, knotted. This differs from the two preceding species in having either all the flowers, or a few of them, growing out into green and purple bundles of leaves. It also frequently produces bunches of reddish leaves, instead of umbels of flowers, in bogs and ditches in the autumn. These leaves seem to put on this appearance from some obstruction in the growth of the plant, occasioned by an insect of the Coccus tribe.—Native of wet heaths and bogs, as of Gamlingay heath, Bullington green, and Eynsham heath.

15. *Juncus Alpinus*; *Alpine Jointed Rush*. Culm leafy; leaves sessile, jointed, knotted; panicle simple; glumes awned.—Native of the Alps, and mountains of Dauphiny.

16. *Juncus Bulbosus*; *Bulbous Rush*. Leaves linear, channelled; capsules blunt; root perennial, horizontal, extremely fibrose; flowers solitary, small, coloured, terminating, most usually in threes, the middle one axillary, sessile. With us, this rush varies in height from two inches to two feet, and is sometimes viviparous. It flowers in August.—Native of wet meadows, heaths, and of the sea-coast.

17. *Juncus Bufonius*; *Toad Rush*. Culm dichotomous; leaves angular; flowers solitary, sessile; root annual, fibrose. It flowers from May to August.—Native of wet, gravelly, or sandy pastures, especially where water stagnates in winter.

18. *Juncus Stygius*. Leaves bristle-shaped, somewhat depressed; peduncles in pairs, terminating; glumes solitary, subbiflorous; root perennial, simple, jointed, with solitary radicles, covered with the remains of the leaves of the preceding year. Linneus obtained it from Lapland.—Native of the woody bogs of Sweden.

19. *Juncus Jacquini*. Leaf awl-shaped; head terminating, four-flowered or thereabouts; root perennial, brown, horizontal, knobbed, sending forth very long fibres perpendicularly.—Native of the Alps, flowering in June.

20. *Juncus Biglumis*. Leaf awl-shaped; glume two-flowered, terminating; root perennial, fibrose, simple, perpendicular.—Native of the Lapland Alps.

21. *Juncus Triglumis*. Leaves flat; glume three-flowered, terminating; culms in tufts, three inches high or more, soft, covered at the base with brown sheaths.—Native of the Lapland Alps, Denmark, Switzerland, Austria, Italy, and Siberia.

22. *Juncus Pilosus*; *Small Hairy Wood Rush*. Leaves flat, hairy; corymb somewhat branched; flowers solitary; root perennial, with numerous brown fibres, and short pointed shoots, so that it is somewhat creeping; culms many, about a span or more in length, nearly upright. This is found only in woods and shady situations, which perhaps accounts for its flowering earlier than any of the others; for unless the season be very unfavourable, it will begin to flower in February, and is not usually out of bloom till the beginning of May.

23. *Juncus Spadiceus*. Leaves flat, hairy from the sheath; flowers very small, corymb, solitary, shortly awned; culm not more than a foot high; root-leaves scarcely two lines in breadth, subhirsute.—Native of the Alps.

24. *Juncus Sylvaticus*; *Great Hairy Wood Rush*. Leaves flat, hairy; corymb decompound; flowers in bundles, sessile. In some situations this species is very large and tall, but it more usually occurs with a stalk little more than a foot high. It is not uncommon in woods, and flowers in May.

25. *Juncus Niveus*; *White-flowered Rush*. Leaves flat, somewhat hairy; corymbs shorter than the leaf; flowers in bundles, the handsomest belonging to this genus; culm three feet high.—Native of the Alps, of Switzerland, &c.

26. *Juncus Campestris*; *Hairy Field Rush*. Leaves flat, somewhat hairy; spikes sessile and peduncled; root perennial, somewhat woody, with numerous blackish fibres, creeping; culm simple, from three to nine inches high; flowers ten or twelve in each spikelet, sessile. They appear in April and May, and ripen seeds in June. It indicates a dry and not luxuriant pasture. The hairs proceed from the edges of the leaves, and appear as if left by some animal in rubbing against it. Most frequently found in dry pastures.

27. *Juncus Spicatus*; *Spiked Rush*. Leaves flat; spike racemed, nodding, composed of many flowers.—Native of Lapland, Denmark, and Scotland.

28. *Juncus Serratus*. Leaves ensiform, flat, serrate, hoary underneath; sheath of the panicle awl-shaped, perfoliate.—Native of the Cape of Good Hope.

29. *Juncus Grandiflorus*. Leaf round; culm one flowered; flower upright, single, naked; scarcely a foot high, very smooth.—Native place unknown.

30. *Juncus Bicornis*. Stalk erect, naked; leaves subcylindrical, canaliculate, plain; involucre ciliate, diphylous, erect; flowers distinct; calix linear, lanceolate, very sharp.—Found in Carolina and Georgia, in sandy wet fields near ponds.

31. *Juncus Setaceus*. Stalk naked, filiform, waving; umbels lateral, compound, with but few flowers; peduncles with many flowers; calix subulate.—Found in low grounds from Virginia to Canada.

32. *Juncus Marginatus*. Leaves plain, glabrous; corymb terminal, simple, proliferous.—Found on dry shady hills in Pennsylvania.

33. *Juncus Polycephalus*. Stalk erect, with but few leaves; leaves nodose, articulate; calices linear, triandrous. There are two varieties; one with thicker leaves, compressed, and the other with subfiliform leaves.—Found in inundated places from Pennsylvania to Carolina.

34. *Juncus Aristatus*. Root bulbous; stalk foliose, erect, compressed; leaves narrow, subcanaliculate; panicles compound.—Found in the low grounds of Georgia and Carolina.

35. *Juncus Tenuis*. Stalk foliose, simple; leaves angulate, subcylindrical; flowers oblong, solitary, sessile.—Found in abundance in Georgia and Carolina.

36. *Juncus Campestris*. Leaves plain, pilose; spikes pedunculate, ovate, somewhat stooping.—Found on dry sunny hills from Pennsylvania to Carolina.

Jungmannia; a genus of the class Cryptogamia, order Algæ.—GENERIC CHARACTER. *Male Flowers*: sessile, clustered on the leaves, stem, and frond. *Calix*: scarcely any. *Corolla*: none. *Stamina*: filamenta hardly any; antheræ ovate, one-celled, gaping at the tip. *Female Flowers*: on the same, or on a separate individual. *Calix*: perianth upright, tubular, truncated, crenated or lacinated. *Corolla*: calyptra sessile, smaller than the perianth, subglobose, closed on every side, membranaceous, tender, crowned by the style, at length bursting at the tip. *Pistil*: germen oblong, involved by the calyptra, sessile; style straight, short, passing through the top of the calyptra; stigma simple. *Pericarp*: capsule seated on a long and very tender bristle, globose, one-celled, at length gaping longitudinally into four valves, which are equal, spreading, permanent. *Seeds*: many, globose, adhering by twisted elastic threads, fixed to the bottom, tip, disk, or margin of the valves. *Observe*. Several germina are often found in one perianth, of which, however, only one grows to

maturity.—Thirty species of these Mosses are arranged in five subdivisions, in the fourteenth edition of the *Systema Vegetabilium*. Hudson enumerates thirty species, in the second edition of his *Flora Anglica*; and Dr. Withering, in his *Arrangement of British Plants*, describes many others, many of which are beautiful objects of microscopic observation.

Jungia; a genus of the class Syngenesia, order Polygamia Segregata.—GENERIC CHARACTER. *Calix*: common many-leaved; leaflets somewhat spreading, linear, obtuse, channelled, shorter than the partial perianth, involving three or four flowers; perianth partial, many-leaved, almost equal, many-flowered; leaflets oblong, channelled, obtuse, upright. *Corolla*: compound, uniform; corollets hermaphrodite, equal; proper one-petalled, funnel-shaped; tube gradually widened; border two-lipped; the exterior division rolled back, longer, linear, toothed at the tip; the interior two-parted; the segments two, upright, sharp. *Stamina*: filamenta five, very short, inserted into the tube; antheræ connate. *Pistil*: germen inferior, linear, cornered; style filiform; stigmas two, revolute, obtuse. *Pericarp*: none. *Calix*: unchanged. *Seed*: solitary, cornered; down long, sessile, feathered. *Receptacle*: chaffy; chaffs resembling the calicine leaflets. ESSENTIAL CHARACTER. *Calix*: common three-flowered. *Receptacle*: chaffy; florets tubular, two-lipped; outer-lip ligulate, inner two-parted.—The only known species is,

1. *Jungia Ferruginea*. Stems woody, covered with a ferruginous down; leaves alternate, petioled, remote, flat, rounded, five-lobed, cordate at the base; lobes rounded, blunt, hirsute, and underneath hairy; panicle terminating, large, decompound; heads of flowers small, heaped.—Native of South America.

Juniperus; a genus of the class Dioecia, order Monadelphia.—GENERIC CHARACTER. *Male*. *Calix*: ament conical, consisting of a common shaft, on which are disposed three opposite flowers in triple opposition, a tenth terminating the ament; each flower has for its base a broad, short, incumbent scale, affixed to the column of the receptacle. *Corolla*: none. *Stamina*: filamenta, in the terminal floscule three, awl-shaped, united below into one body; in the lateral flowers scarce manifest; antheræ three, distinct in the terminal flower, but fastened to the calicine scale, in the lateral ones. *Female*. *Calix*: perianth three-parted, very small, growing to the germen, permanent. *Corolla*: petals three, permanent, rigid, acute. *Pistil*: germen inferior; styles three, simple; stigmas simple. *Pericarp*: berry fleshy, roundish, marked on the lower part with three opposite obscure tubercles, from the calix having grown there, and at the tip by three teeth, which before were the petals, umbilicated. *Seed*: three ossicles, convex on one side, cornered on the other, oblong. ESSENTIAL CHARACTER. *Male*. *Calix*: of the ament a scale. *Corolla*: none. *Stamina*: three. *Female*. *Calix*: three-parted. *Petals*: three. *Styles*: three. *Berry*: three-seeded, irregular, with the three tubercles of the calix.—The species are,

1. *Juniperus Thurifera*; *Spanish Juniper*. Leaves imbricate in four rows, acute. It grows to the height of twenty or thirty feet. Berries very large, black when ripe.—Native of Spain and Portugal. This, like all the other plants of this genus, may be propagated by sowing the seeds as soon as they are ripe, if they can be procured; for if kept until the spring before they are sown, they will not come up till the second year. The ground in which the seeds of the hardy sorts are sown, should be fresh and light, but it should not be dunged; when it is well dug and levelled, sow the seeds pretty thick, and sift some earth over them to the depth of half an inch; this bed will only require weeding,

and, towards the middle or latter end of April, some of the plants will appear above ground, though probably the greatest part of them may lie till the following spring before they come up; therefore the beds should be carefully weeded, and watered in very dry weather, which will greatly promote the growth of those plants that are up, and also cause the other seeds to vegetate; but if the bed in which these are sown, is much exposed to the sun, it should be shaded with mats in the day, for, when the plants first come up, they will not bear much heat. In this bed they should remain till the next spring, or second autumn, when you must prepare beds, into which they are to be transplanted; they should be also of light, fresh, undunged soil, well dug, cleansed from all noxious weeds, and levelled. In the beginning of October, which is the proper season for removing these plants, raise them up with a trowel, preserving as much earth as possible to their roots, and plant them into beds about five or six inches asunder each way, or eighteen inches by nine or ten, giving them some water, to settle the earth to their roots: if it should prove very dry weather, you must lay a little mulch upon the surface of the ground, round their roots, which will be very serviceable to the plants; but, as many of the seeds will be yet left in the ground where they are sown, the beds should not be disturbed too much, in taking up the plants; they may remain two years in these beds, observing to keep them clear from weeds: in the spring, stir the ground between them gently, that their roots may the more easily strike into it; after that, they should be transplanted, either into a nursery, at the distance of three feet row from row, and eighteen inches asunder in the rows, or into the places where they are to remain: the best season for transplanting them, we have already observed, is in the beginning of October: they should then be carefully taken up, preserving a ball of earth to their roots, and, when replanted, the roots should be mulched, which, if carefully attended to, and watering them in dry weather till they have taken root, will ensure their growth. They are extremely hardy in bearing cold, and will survive our severest winters, if planted in a moist or rich soil. Most of them may also be propagated by cuttings, which, if planted in autumn, or at the end of August, in a shady border, will take root: but those plants which are raised from cuttings will never grow so upright, nor to so large a size, as the plants that are raised from seeds; so that raising them by cuttings is practised on those only which do not perfect seeds in England. As several species grow to the height of eighteen or twenty feet, the procuring as many of the sorts as can be gotten from the countries of their growth, will be adding to the variety of our evergreen plantations, which cannot be too much propagated in England, where the winters are in general so temperate, that that they may thrive to advantage; almost all of them are hardy enough to live in the open air, and are well worth propagating, as they add to the variety of evergreen plantations, and especially as some of them rise to such a height that they may produce much useful timber, and may be adapted to such soils as will not suit any other trees. The tender sorts may also acquire strength to resist the frost, for we find many plants, that will not live in the open air when first imported, become naturalized, and defy the severest cold of our variable climate. In order to increase the height of these trees, their under branches should be taken off, especially where they are inclined to grow strong; but they must not be kept very closely pruned, for that would retard their growth. All these evergreen trees do more or less abound with a resinous juice, which, in hot weather, is very apt to flow out from such places as are wounded; so that it

will not be advisable to take off many branches at once, especially in hot weather, when their sap would flow so plentifully as to render the trees weak and unhealthy.

2. *Juniperus Barbadensis*; *Barbadoes Juniper*. All the leaves imbricate, in four rows, the younger ovate, the older acute. This has been confounded with the next species: the berries are smaller, and of a light brown colour when ripe.—It is a native of the West Indies, where it rises to be one of the largest timber trees; the wood is frequently fetched from thence by the inhabitants of North America, for building ships. For its propagation and culture, see the preceding species.

3. *Juniperus Bermudiana*; *Bermudas Juniper*. Lower leaves in threes, upper in pairs, decurrent, awl-shaped, spreading, acute. The berries are produced towards the end of the branches, and are of a dark red colour, inclining to purple. The wood has a very strong odour, and was formerly in great esteem for wainscoting rooms, and also for furniture.—Native of America. Dr. Patrick Browne says that it grows very plentifully in most of the blue mountains of Jamaica, where it is frequently cut down for planks. He says it is a good timber wood, admired for its smell, lightness, close even grain; and very fit for wainscoting, and all the inward parts of cabinet work. It is of a reddish colour, very sweet, and commonly known in England by the name of Cedar-wood. There are several sorts of wood called by that name, but this is the wood used for pencils, wainscoting rooms, and building staircases, because it continues sound longer than most other sorts of timber, which is perhaps owing to something extremely bitter in the resin with which the tree abounds; for it is very remarkable, that worms do not eat the bottoms of the vessels built with this wood, as they do those that are built with oak, so that vessels built with it are the best for the West Indian seas; but unfortunately the wood is so brittle, and splits so much when struck with a cannon-ball, that it would not at all answer for ships of war. This tree is not only a native of Bermuda, but of the Bahamas. They are propagated by seeds, in the same way as the first species, except that they should be sown in pots or tubs of earth, that they may be removed into shelter in the winter time, otherwise the young plants will be injured by hard frosts; but they will only require to be placed under a common hot-bed frame, where the glasses may be kept off, and the free air constantly admitted in fine weather: these seeds always remain in the ground till the second year before they come up, therefore the earth in the pots should not be disturbed; and in the summer time they should be placed in the shade, to prevent the earth from drying too fast; they should be often watered in very dry weather, but in small quantities at each time: the next spring, when the plants come up, they must be carefully cleared from weeds, and in dry weather refreshed with water; but should stand during the summer in a place defended from strong winds; and in winter, must be placed under frames, where they may be covered in hard frosty weather, but must have free air when the weather is mild: in the following April, transplant them each into a single halfpenny pot filled with fresh light earth, being careful to raise them up with a ball of earth to their roots; and when they are planted, water them, to settle the earth to the roots, and place the pots in a warm situation, defended from sun and wind; but if you can conveniently plunge the pots into a moderate hot-bed, it will greatly promote their taking new root: they must be screened from the powerful heat of the sun till they have taken root, and may then be gradually exposed to the open air; if you suffer the pots to remain

plunged all the summer, it will preserve the earth in them from drying so fast as it would, if they were set upon the ground. In October, you should again remove these plants into shelter, or else plunge their pots into the ground, under a warm hedge, where they may be protected from the cold north and east wind; and in the spring following, you must shift the plants into pots of a larger size, taking away some of the earth from the outside of the ball, and adding some fresh: after this, continue to manage them as was before directed, until you plant them out in the places where they are designed to remain, which should not be done till they are four or five years old, by which time they will be strong enough to bear the cold of our common winters. The reason for directing these plants to be preserved in pots, until they are planted out for good, is, because they are difficult to transplant, and, being tender, will require some shelter while young: and whoever observes the method here laid down, will find the plants so managed to gain two years growth in six, from those raised in the open air, besides being less liable to be destroyed; and as the trouble and expense of raising them this way is not great, it is worth practising, since in a few years the trees will recompense the trouble.

4. *Juniperus Chinensis*; *Chinese Juniper*. Leaves decurrent, imbricate, spreading, clustered; stem-leaves in threes; branch-leaves in fours. A shrub three feet high.—Native of China. For propagation and culture, see the first species.

5. *Juniperus Sabina*; *Savin*. Leaves opposite, erect, decurrent, the oppositions boxed. Mr. Miller makes two species of the Common Cypress-leaved, and Tamarick-leaved, or Berry-bearing Savin, as he calls it: the former, he says, has been erroneously supposed to be a mere variety. It rises to the height of seven feet, and produces great quantities of berries, whereas the latter very rarely produces either flowers or seeds in our gardens, and seldom rises more than three or four feet high, sending out its branches horizontally to a considerable distance every way. The berries are smaller than those of the Common Juniper, and the whole plant has a very rank odour when handled.—Native of the south of Europe, and the Levant. It is more powerful in its operations, as a medicine, than the Common Juniper, and has been much famed as an emmenagogue: it heats and stimulates the whole system very considerably, and is said to promote the fluid secretions. The leaves and tops have a very strong disagreeable smell, and a hot bitterish taste; they give out their active matter to watery liquors, and still more completely to rectified spirit. When distilled with water, they yield a large quantity of essential oil. Decoctions of the leaves inspissated to the form of an extract, retain a considerable share of their pungency and warmth, together with their bitterness, and have some degree of smell, but not resembling that of the plant itself. On inspissating the spirituous tincture, there remains an extract consisting of two distinct substances; of which one is yellow, oily, bitterish, and very pungent; the other black, resinous, tenacious, less pungent, and very astringent. Though Savin has sometimes failed when used as an emmenagogue, it has also been sometimes found too powerful, so as to produce dangerous consequences. Dr. Home used it with great success in cases of amenorrhœa, given in powder, from a scruple to a drachm thrice a day. Upon the whole, therefore, Savin may be considered as a warm stimulant and aperient, particularly serviceable in uterine obstructions, proceeding from a laxity of the vessels, or a cold sluggish disposition of the juices. The distilled oil, in addition to the powers just mentioned, in doses of two or three drops, is a strong diuretic, and

and impregnates the urine with its smell. Country people give the juice, mixed with milk, to their children, in order to destroy the worms, which it generally carries off by stool. The leaves cut small, and given to horses mingled with their corn, destroys those troublesome vermin called the bots. It may be propagated by slips, which will grow at any time. The upright Savin also may be propagated by slips planted in moist weather in August, and kept shaded, and watered in dry weather afterwards. The striped Savin must be increased in the same way, from the branches which are the most variegated; they may also be raised by berries, when the plants produce any, and from these the most upright and best plants are raised. The Common Savin should not be neglected, because it is so very hardy as never to be injured by the severest frosts; and, as it spreads its branches near the ground, if the plants be placed on the borders of woods, they will have a good effect in winter, by screening the nakedness of the ground from sight.

6. *Juniperus Virginiana*; *Virginian Juniper*, or *Red Cedar*. Leaves in threes, fastened at the base, the younger ones imbricate, the older spreading. Mr. Miller has two species. The first, he says, grows naturally in most parts of North America, where it is called Red Cedar, to distinguish it from a sort of Cypress, which is there called White Cedar; of this there are two varieties, one that has leaves in every part like the Savin, and, upon being rubbed, emits a very strong ungrateful odour; this the Americans call Savin Tree: the other has leaves very like those of Cypress—but both are probably mere seminal varieties. The second of Miller's species has leaves like the Swedish Juniper, and under leaves like those of the Cypress; which difference it constantly retains. Sloane says it grows to be one of the largest and highest timber-trees in Jamaica, affording very large boards of a reddish-brown colour, close and firm texture, shining, very odoriferous, extremely like Bermudas Cedar, but being towards its outsides of a paler colour, and looser texture; the bark is thin, and ready to drop off in great pieces, appearing somewhat contorted, of a reddish-brown colour. This tree is much used for wainscoting rooms, making escrutoires, cabinets, &c.; cockroaches and other insects disliking the smell of it. In its native country it grows to a great height, and affords excellent timber for many uses; but with us there are very few trees that exceed thirty feet high, though there is no doubt of their growing larger, for they thrive very fast after the first three years. They are propagated by seeds, which must be procured from Virginia or Carolina, (for they seldom produce seeds in England,) and sown as was directed for the other Junipers; but as this seed cannot be procured in England till spring, so, when sown at that season, it remains in the ground until the succeeding spring before the plants appear; the beds therefore must remain undisturbed, and be kept clear from weeds, for it is sometimes two years after sowing before they come up; when the plants appear, they must be carefully weeded, and refreshed with water in dry weather, to forward their growth: in the following autumn, they should have a little rotten tan laid between them, to keep out the frost; in this bed the plants may remain till they have had two years' growth; they should then be transplanted into other beds, as directed for the other species, observing to preserve a ball of earth to their roots, and, after they are planted, to water them carefully in dry weather, and cover the surface of the ground with mulch, to prevent the sun and wind from drying the earth so as to affect their roots; they may remain two years in these beds, keeping them clear from weeds, and in winter laying fresh mulch upon the

surface of the ground round their roots, to preserve them from frost, by which, while the plants are so young, they are liable to be injured, if much exposed; but when they have acquired strength, they will resist the severest of our cold; after two years, they should be either removed into the nursery, as was directed for the first species, or transplanted where they are intended to remain, observing always to take them up carefully, otherwise they are subject to fail upon transplanting; as also to mulch and water the ground as before, until they have taken root; after which, they will require no further care, than only to keep the ground clear about their roots, and to prune up their side branches to make them aspire in height. The soil in which these trees are finally planted, should be fresh and light, but must not be dunged, especially at the time when they are planted, for dung is very injurious to them, unless it be quite rotted to mould: hence the mulch laid upon the surface of the ground should not be dung, but rather some old tanner's bark, or sea-coal ashes, which will prevent the frost from penetrating deep into the ground. These trees being thus managed, will, in a very few years, rise to a considerable stature, and will resist the sharpest frost of our climate exceedingly well. The variety of their evergreen leaves, and manner of growth, will greatly add to the beauty of all plantations, where they are rightly disposed; unfortunately, however, there are few persons who consider the different growth of the several trees with which they compose such plantations, so as to place the tallest-growing trees the backwardest from sight, and the next tallest next to them, gradually diminishing, till we come to the Common Juniper, and others of the same growth; whereby all the trees will be seen, and the gradual declivity of their tops will exhibit a verdant slope, and be much more agreeable to the sight, as well as more advantageous to the growth of the trees, than to place shrubs of humble growth near such plants as will grow to the first magnitude, and not only hide the shrub from sight, but overshadow and destroy it: nor can the distance which each requires be so justly proportioned any other way; for in this distribution the larger trees being separated by themselves, may be placed at a due distance; and then, those of a middling growth succeeding, may be accordingly allowed sufficient room; and the smaller, which are next the sight, being placed much closer, will hide the naked stems of the larger trees, and produce an agreeable effect to the eye.

7. *Juniperus Communis*; *Common Juniper*. Leaves in threes, spreading, mucronate, longer than the berry. It is a low shrub, seldom rising above three feet high; the male flowers are sometimes on the same flowers with the female, but at a distance from them: but they are commonly on distinct plants. The female flowers are succeeded by roundish berries, which are first green, but, when ripe, of a dark purple colour. There are two varieties, the Swedish or Tree Juniper, and the Alpine or Mountain Juniper, which are scarcely to be distinguished from the common sort; the first varies with narrower leaves and longer berries, the second with broader and thicker leaves and oval berries. When planted in a good soil, it will rise fifteen or sixteen feet high, and form a well-looking bushy shrub, which is easily transplanted, and bears cropping. Grass will not grow beneath it, but the *Avena Pratensis* destroys it. The wood is hard and durable, and the bark may be made into ropes. Spirit, impregnated with the essential oil of these berries, is every where known by the name of Juniper water, or *Gin*. Gum Sandarach, known under the name of Pounce, in its powdered form, is the produce of this shrub. Horses,

sheep, and goats, feed upon this plant; several insects, as the *Crinea Juniperinus*, *Thrips Juniperina*, and *Coccinella Novempunctata*, live upon it; indeed, sometimes the leaves of the calix grow double the usual size, approaching, but not closing, and the three petals fit exactly close, so as to keep the air from the *Tipula Juniperi*, or Juniper Spiders, which inhabit them. This plant is celebrated for its diuretic properties. The berries are principally used: a spirit prepared from them is kept in the shops, and used plentifully in hydropic cases, and in diuretic draughts; these berries, boiled in water, yield a sweet decoction, tasting very strongly of the juniper; from this decoction, a quantity of sugar may be obtained: the berries are also considered as stomachic, carminative, and diaphoretic; of their efficacy in many hydropical affections, we have various relations from physicians of high authority, such as Du Verney, Boerhaave, Hoffman, and Van Swieten. Authors, however, do not seem agreed which preparation of the Juniper is most efficacious; some preferring the rob or inspissated decoction, of which the celebrated Cullen disapproved, alleging, that in the boiling it loses great part of its essential oil, in which he thought the virtue of Juniper principally consisted. Hoffman, on the other hand, strongly recommends the rob, which he declares to be of great utility in weakness of the stomach and intestines, especially for elderly persons; but as the modern practice generally depends on more powerful medicines, the Juniper being considered in a secondary view, it may perhaps be allowed that as good a form as any for its use, is that of a simple decoction, which either by itself, or with the addition of a small quantity of gin, may be a useful drink for hydropic patients. Medical writers have also recommended it in scorbutic cases, and in some cutaneous diseases; but in these cases, a decoction, prepared from the wood and the tops of the plant, is thought preferable to that from the berries. Linneus informs us, that his countrymen, the Swedes, prepared a beer from the berries, which they consider as very efficacious in scorbutic cases, and that the Laplanders drink infusions of Juniper berries as we do tea and coffee, for the same purpose. Hill says, the berries are excellent in colicky complaints, and for the stone and gravel. He agrees with Hoffman in observing, that the rob or jelly made from the berries is excellent in catarrhs, defluxions or humours on the lungs and breast, weakness and debility of the stomach and intestines, difficulty of making water in people of an advanced age, and other similar disorders. Juniper wine is sometimes made, and is said to be very wholesome. For the propagation and culture, see the detail under the first species.

8. *Juniperus Oxycedrus*; *Brown berried Juniper*. Leaves in threes, spreading, mucronate, shorter than the berry; height ten or twelve feet, branched the whole length. This shrub will be feathered from top to bottom, if left untouched from the first planting, and not crowded with other trees. The leaves are awl-shaped, and finely spread open; they are also very short, sharp-pointed, and give the shrub a fine look; and the large brownish-red berries make a handsome appearance when they are ripe.—Native of Spain, Portugal, and the south of France. See the first species.

9. *Juniperus Phœnicea*; *Phœnician Juniper*, or *Cedar*. Leaves in threes, obliterated, imbricated, obtuse; it grows with the branches in a pyramid. Ray thinks it scarcely distinct from the following species.—Native of the south of Europe, and the Levant. Mr. Miller takes it to be a native also of Portugal.

10. *Juniperus Lycia*; *Lycian Juniper*, or *Cedar*. Leaves in threes, imbricate on all sides, ovate, obtuse; branches

erect, covered with a reddish-brown bark. Pallas says it is difficult to distinguish it from the Savin, that the bruised leaves have the same smell, and the principal difference consists in the greater thickness of the shoots, and in the leaflets being acute and less clustered. He says the leaves are never in threes with them.—Native of the south of France, the Levant, and Siberia. This is the species from which the gum resin called *Olibanum* is obtained. It has a strong smell, and a somewhat bitterish and pungent taste. Though not the same substance as is sold by the above name in the shops, it is supposed to have been the incense used by the ancients in their religious ceremonies, and has been adopted by their Roman Catholic successors for similar uses. As a medicine, it has chiefly been used in disorders of the head and breast, and in hæmoptoes, and alvine and uterine fluxes, from a scruple to the amount of a drachm or more each dose. It has also been employed in plasters, and as an ingredient in various pills. See the first species.

11. *Juniperus Drupacea*. Leaves in threes, spreading, acute, three times shorter than the drupe; nut three-celled; stem frutescent, erect, branched; branches spreading; branchlets three-sided.—Native of Mount Cassius; and probably the same with the Great Juniper observed by Belon on Mount Taurus, and which he describes as rising to the height of a Cypress, and bearing a sweet fruit, the size and shape of an olive. See the first species.

12. *Juniperus Daurica*; *Siberian Juniper*. Leaves opposite, acute, imbricate, decurrent, spreading, awl-shaped. This is usually shrubby, with the stems lying prostrate on the rocks, the principal ones often the thickness of the human arm; branches thickish, testaceous; shoots green, dichotomous.—Native of Siberia.

Jupiter's Beard. See *Anthyllis*.

Jussieua; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-cleft, superior, small; leaflets ovate, acute, permanent. *Corolla*: petals five, roundish, spreading, sessile. *Stamina*: filamenta ten, filiform, very short; antheræ roundish. *Pistil*: germen oblong, inferior; style filiform; stigma headed, flat, marked with five streaks. *Pericarp*: capsule oblong, crowned, five-celled, gaping at the corners. *Seeds*: very many, disposed in rows. *Observé*. Species exist in which a fifth part of the number is wanting. ESSENTIAL CHARACTER. *Calix*: four or five-parted, superior. *Petals*: four or five. *Capsule*: four or five-celled, oblong, gaping at the corner. *Seeds*: numerous, minute.—The species are,

1. *Jussieua Repens*; *Creeping Jussieua*. Creeping: flowers five-petalled, stamined; leaves ovate oblong; roots simple, filiform, short. The flowers are small and yellow. There is a variety with herbaceous, ascending, simple, even stems. They flower in spring.—Native of moist watery places in Jamaica, where, Browne says, it is frequent in our low lands about Plantain-garden river. This, with all the plants of this genus, should be sown early in the spring, in pots filled with a soft loamy soil, and plunged into a moderate hot-bed; but as the seeds often lie a whole year in the ground before they vegetate, the earth must be kept moist, and the glasses of the hot-bed shaded in the heat of the day, by which means their vegetation will be hastened. When the plants come up, and are fit to remove, they should be each planted into a small separate pot filled with light loamy earth, and plunged into a hot-bed of tanner's bark, where they should be shaded from the sun till they have taken new root, after which they should have free air admitted to them every day, in proportion to the warmth of the season. Water should be frequently given, but in small quantities. When the roots

of the plants have filled these small pots, the plants should be removed into others a size larger, and if too tall to stand under the frames of the hot-bed, must be placed in the bark-stove, where they may remain to flower and perfect their seeds: for when the plants rise early in the spring, and are brought forward in hot-beds, all the sorts will flower, and perfect their seeds in the same year; which is better than to have them keep through the winter.

2. *Jussieua Tenella*. Smooth: flowers five-petalled, subsessile; leaves opposite, linear, lanceolate, quite entire.—Native of Java.

3. *Jussieua Peruviana*; *Peruvian Jussieua*. Upright: flowers five-petalled; peduncles leafy.—Native of Lima.

4. *Jussieua Pubescens*; *Hairy Jussieua*. Upright, villose: flowers five-petalled, ten-stamined, sessile; stem usually brown, strong, four or five feet high, having several hairy, red, angular branches.—Native of Jamaica.

5. *Jussieua Suffruticosa*; *Shrubby Jussieua*. Upright, villose: flowers four-petalled, eight-stamined, peduncled. The shrubby stalk rises three feet high, and sends out several side-branches; petals yellow.—Native of India.

6. *Jussieua Erecta*; *Upright or Red-stalked Jussieua*. Upright, smooth: flowers four-petalled, eight-stamined, sessile; root annual; stem from two to four feet high, herbaceous, very much branched, four-cornered, smooth, reddish. Colour of the flowers yellow.—It is a vernal marsh-plant, native of Jamaica, and of other West India Islands; of the American Continent; and also of the East Indies, in Ceylon, Java, and Japan.

7. *Jussieua Inclinata*. Upright, smooth: flowers four-petalled, eight-stamined, peduncled; stem simple, round, thick, porous, watery, rooting at the lower joints; peduncles one-flowered.—Native of the marshes of Surinam.

8. *Jussieua Octovalvis*. Upright: flowers four-petalled, eight-stamined, peduncled; capsules many-valved; leaves lanceolate, acuminate; flowers on short peduncles, large, yellow; seeds very many, roundish.—Native of South America and the West Indies, in marshy watery places. See the first species, for this and the six preceding.

9. *Jussieua Hirta*. Upright, hirsute: flowers four-petalled, eight-stamined; leaves ovate, acuminate, rough-haired underneath; stem hispid; branches hispid, alternate.—Native of South America and Jamaica. See the first species.

10. *Jussieua Onagra*. Upright, smooth, branching: flowers four-petalled, eight-stamined, sessile; leaves lanceolate.—Native of South America. See the first species.

11. *Jussieua Hirsuta*. Upright, hirsute, simple: flowers five-petalled, ten-stamined, sessile; leaves lanceolate; stalks red, three feet high, hairy, channelled; petals yellow.—Native of La Vera Cruz. See the first species.

12. *Jussieua Grandiflora*. Leaves very entire; lower leaves spatulate; upper leaves lanceolate; flowers decandrous, large, and yellow; peduncles and calices villose; roots creeping.—Found in the swamps of Virginia and Carolina, about the Dismal Swamp. See the first species.

13. *Jussieua Subacaulis*. Leaves linear-lanceolate; flowers solitary, octandrous, pedunculated, small, and yellow; filamenta alternate, very short; petals obovate.—Found by Lewis on the banks of the Missouri.

Justicia; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, very small, five-parted, acute, upright, narrow. *Corolla*: one-petalled, ringent; tube gibbose; border two-lipped; lip superior, oblong, emarginate; lip inferior, of the same length, reflex, trifid. *Stamina*: filamenta two, awl-shaped, hid under the upper lip; antheræ upright, bifid at the base. *Pistil*:

germen top-shaped; style filiform, length and situation of the stamina; stigma simple. *Pericarp*: capsule oblong, obtuse, narrowed at the base, two-celled, two-valved; the partition opposite to the valves, gaping, with an elastic claw. *Seeds*: roundish. *Observe*. The upper lip of the corolla differs in point of situation. Some species also recede so much from this character as to seem a distinct genus. **ESSENTIAL CHARACTER.** *Corolla*: ringent. *Capsule*: two-celled, opening with an elastic claw. *Stamina*: with a single anther. It appears from the recent observations of Jacquin, Jussieu, Vahl, and others, that the two antheræ on each filamentum are not a sufficient generic distinction; for in some species of *Dianthera* the filaments are divided into two segments, each of which has an anther; but in others the filaments are undivided, and have two antheræ indeed, but so approximated as almost to coalesce into one. But not only *Diantheræ*, properly so called, have two antheræ, but most of the *Justiciæ*, if not all, are really *Diantheræ*; for several, not enumerated by Linneus, as the sixty-fourth and fifth species of this genus, have two antheræ quite distinct, but the rest have generally twin or double antheræ, with this difference, that, being parallel to each other, they seem to be but one, although they are really two. If this natural genus, consisting of *Justicia* and *Dianthera*, is to be separated, Vahl recommends it to be grounded on the capsule rather than the antheræ.—The species are,

* *With a double Calix.*

1. *Justicia Fastuosa*; *Superb Justicia*. Shrubby: leaves lanceolate-elliptic; flowers in terminating thyrses; calices two-flowered; stem smooth, round, and even.—Native of Arabia Felix, and the island of St. Johanna. This, like most of the plants of this genus, may be propagated from seeds, and also increased from cuttings.
2. *Justicia Forskahlei*. Shrubby: leaves ovate, acuminate; flowers in axillary and terminating thyrses; calices one-flowered.—Native of Arabia Felix. See the preceding.
3. *Justicia Purpurea*. Herbaceous: branches pubescent; flowers in axillary and terminating spikes; bractes lanceolate, smooth; stem rooting, brachiate; corollas purple.—Found near Canton in China. See the first species.
4. *Justicia Verticillaris*. Villose: leaves ovate; flowers axillary, in whorls; outer calices awnless.—Native of the Cape of Good Hope. See the first species.
5. *Justicia Aristata*. Villose: leaves ovate; flowers axillary, in whorls, subsessile; outer calices awned.—Native of the Cape of Good Hope. See the first species.
6. *Justicia Chinensis*. Herbaceous: leaves ovate; peduncles axillary, in whorls, trifid; bractes ovate, mucronate, coloured at the base; stems procumbent; corolla pale violet-colour.—Native of China. See the first species.
7. *Justicia Triflora*. Herbaceous: leaves ovate; peduncles axillary, elongated, subtriflorous; bractes linear, lanceolate.—Native of Arabia Felix. See the first species.
8. *Justicia Serpens*. Herbaceous, creeping: leaves oblong, smooth; flowers axillary, solitary; stem filiform.—Native of the Isle of France. See the first species.
9. *Justicia Sulcata*. Herbaceous: leaves ovate, cordate; spikes terminating; flowers in whorls. See *Dianthera Sulcata*.
10. *Justicia Bicalyculata*. Leaves ovate-acuminate; flowers in axillary dichotomous panicles; outer bracte linear, double the length of the other; antheræ binate; flowers purple.—Native of the East Indies. See the first species.
11. *Justicia Bivalvis*. Shrubby: leaves ovate-lanceolate; peduncles axillary, trifid, lateral; pedicels two-flowered; bractes ovate, awned, nerved; capsule villose.—Native of the East Indies and Arabia Felix. See the first species.

** *With a single Calix.*—*Corollas two-lipped; lips undivided.*

12. *Justicia Sexangularis*; *Chick-weed-leaved Justicia*. Herbaceous: leaves ovate; peduncles three-flowered; bractes wedge-shaped; antheræ parallel. The flowers appear in small spikes at the sides of the branches, and are of a beautiful carmine colour; stalk upright. It is annual, and a native of La Vera Cruz and Jamaica.—It may be propagated by seeds sown early in the spring, in small pots filled with light fresh earth, and plunged into a moderate hot-bed of tanner's bark, observing to water the earth gently when it appears dry. As the seed frequently lies a year in the ground, the pots must not be disturbed in case they should not immediately appear. In the winter, they should be kept in the stove, and the spring following plunged into a fresh hot-bed. When the plants begin to appear, the glasses of the hot-bed should be raised every day in warm weather, to admit fresh air; they ought also to be frequently watered at the same time, but in small quantities while they are young, as they are subject to rot at bottom with much moisture. When the plants are about two inches high, take them up carefully, and transplant each into a small pot filled with fresh light earth, plunging them into the hot-bed again, and watering and shading them till they have taken new root: then they should have air admitted every day in proportion to the warmth of the season, and should be duly watered every two or three days in hot weather. As the plants advance in their growth, they should be shifted into larger pots; for when their roots are too much confined, they will not make any considerable progress. To over-pot them, however, would be of still worse consequence than the other, because, when they are planted in very large pots, they will starve, and decay, without producing any flowers. They are too tender to endure the open air in this country; this species in particular should always remain in the hot-bed, and be brought forward as far as possible in the spring, that they may flower early, otherwise they will not produce good seeds in England.

13. *Justicia Scorpioides*. Shrubby: branches round; leaves lanceolate, ovate, hirsute, sessile; spikes axillary, recurved; bractes minute; antheræ parallel; flowers large, of a carmine colour, and ranged on one side of the spike; stem brittle, five or six feet high, sending out many branches.—Discovered at Vera Cruz. For its propagation and culture, see the preceding species. This and the seventy-ninth species should remain in the hot-bed during the summer season, provided there be room for them under the glasses without being scorched; but at Michaelmas they should be removed into the stove, and plunged into the bark-bed, where they must remain during the winter season, observing to keep them warm, as also to water them gently once or twice a week, according as they shall require. The following summer these plants will flower, and abide several years; but they rarely produce good seeds in Europe.

14. *Justicia Assurgens*. Herbaceous: branches angular; leaves ovate, elliptic; spikes axillary and terminating, branched; flowers alternate; bractes linear; antheræ parallel.—Native of Jamaica. See the first species.

*** *Corollas two-lipped; lower lip divided.*

15. *Justicia Acaulis*. Stemless: leaves crenate; veins villose underneath; root pubescent, woolly at top.—Native of the East Indies. See the first species.

16. *Justicia Ecbolium*; *Long-spiked Justicia*. Shrubby: spikes terminating, four-cornered; bractes ovate, imbricate, ciliate, mucronate; upper lip linear, reflex; antheræ parallel; stem roundish, compressed, jointed. Mr. Miller says that it rises ten or twelve feet high in its native soil; and that the flowers grow from the ends of the branches in very

long spikes, and are of a greenish colour with a shade of blue.—Native of the East Indies, and Cochin-china. This is propagated in the same way as the twelfth species, but may be more hardily treated when the plants have obtained strength. It may also be increased by cuttings, as is directed for the sixty-fourth species, and when the plants are two or three years old, they will thrive with a moderate degree of warmth in winter. In summer they may be placed abroad two months during the warmest season, but always in a sheltered situation; and when the nights begin to grow cold, they must be removed into the stove, but still have free air admitted to them in warm weather.

17. *Justicia Pulcherrima*. Shrubby: spikes axillary, and terminating; bractes ovate-imbricate, ciliate, awnless; upper lip lanceolate, straight; stem upright, five or six feet high; flowers without smell, in four rows, of a fine bright red.—Native of South America, near Carthage.

18. *Justicia Carthaginensis*. Herbaceous: leaves elliptical; spikes axillary and terminating; bractes imbricate, all wedge-shaped, ciliate; upper lip emarginate; antheræ binate. This appears to be an annual plant. It is upright, growing six feet high among bushes and in hedges, but only three feet in other situations; flowers void of scent, purple.—Native of Carthage, in Spanish America.

19. *Justicia Tetragona*. Shrubby: leaves crenate, smooth; spikes terminating, four-cornered; bractes ovate, imbricate, in four rows, keeled, ciliate; branches round, smooth, opposite.—Sent from Cayenne.

20. *Justicia Coccinea*; *Scarlet-flowered Justicia*. Shrubby: leaves and bractes elliptical, acuminate; upper lip undivided; antheræ parallel; stem six feet high, nearly erect, round, covered by a smooth brown bark, cracking longitudinally; spikes terminating, mostly solitary, erect, simple, dense, many-flowered; flowers sessile, one between each pair of the smaller bractes, erect, large, handsome, scarlet, becoming tawny in decay. They are only to be found on old plants, and have no smell. The leaves when bruised have an herbaceous scent. This is the largest species known in England, and, when cultivated, grows in the hot-house almost to the size of a tree.—Native of South America.

21. *Justicia Hirsuta*. Herbaceous: leaves toothed; spikes axillary and terminating, four-cornered; bractes ovate, imbricate, hirsute; flowers opposite, with two bristle-shaped bractes at the base.—Native of Java.

22. *Justicia Sphaerosperma*. Herbaceous: spikes axillary, opposite, in pairs on each side; bractes linear, elongated; seeds globular, shining; branches round.—Native of the Caribbee islands.

23. *Justicia Gandarussa*. Shrubby: leaves lanceolate, elongated; spikes terminating, leafy; flowers in whorls; bractes minute; upper lip undivided; antheræ binate; stem smooth, round.—Native of the East Indies.

24. *Justicia Procumbens*. Herbaceous: stem procumbent; leaves lanceolate, quite entire; spikes axillary and terminating; calices four-cleft.—Native of Ceylon and Java.

25. *Justicia Echioides*. Herbaceous: leaves lanceolate-linear, rough-haired; spikes axillary, opposite, pointing one way, ascending; antheræ parallel, bearded at the base.—Native of the East Indies.

26. *Justicia Longifolia*. Herbaceous: leaves lanceolate, elongated; spikes axillary, in pairs, opposite, pointing one way; stem smooth; flowers alternate; corolla small.—Native of the island of Mahe.

27. *Justicia Latifolia*. Shrubby: leaves ovate, acuminate; spikes terminating, somewhat branched; lower flowers in whorls; branches round, smooth.—Native of the East Indies.

28. *Justicia Picta*. Shrubby: leaves ovate, painted; spikes axillary, and terminating; flowers in whorls; upper lip bifid; antheræ parallel; stem striated, eight feet high; corolla red.—Native of the East Indies.

29. *Justicia Nitida*. Shrubby: leaves elliptic, acuminate; racemes spike-form, whorled; bractes minute; pedicels and calices smooth; antheræ parallel.—Native of the West Indies, in Martinico, Guadaloupe, and Santa Cruz.

30. *Justicia Stricta*. Herbaceous: leaves lanceolate, elliptic; racemes axillary, two-parted, pointing one way; filaments smooth; stem smooth, quadrangular; flowers small.—Native of Malabar.

31. *Justicia Paniculata*. Herbaceous: leaves lanceolate; panicles axillary and terminating, dichotomous; flowers pointing one way; filaments hirsute; capsules compressed.—Native of the East Indies.

32. *Justicia Nutans*. Herbaceous: leaves toothed; racemes terminating, nodding at top; flowers inverted.—Native of Java.

33. *Justicia Nasuta*. Suffrutescent: leaves elliptic, quite entire; peduncles axillary, dichotomous, upper lip upright, bifid; antheræ divaricating.—The bruised leaves are used in the East Indies, where it is a native, for the cure of cutaneous eruptions.

34. *Justicia Scandens*. Shrubby: leaves ovate, acuminate, subrepand; branches villose; peduncles axillary, trichotomous, divaricating. It varies with the branches and veins of the leaves less villose.—Native of Malabar. See the first species, for this and the 17 preceding.

35. *Justicia Ciliaris*; *Ciliated Justicia*. Herbaceous: leaves lanceolate, bluntish; flowers axillary, opposite; antheræ parallel, appendicled. The whole plant is rugged. It flowers throughout the summer.—Native place of growth unknown.

36. *Justicia Secunda*. Herbaceous: leaves ovate, lanceolate-acuminate; racemes terminating, compound; racemelets pointing one way; antheræ binate; flowers on the racemelets alternate, four or five, on short pedicels; corolla purple.—Native of the island of Trinidad. See the first species.

37. *Justicia Debilis*. Shrubby: spikes axillary and terminating; bractes ovate, imbricate, ciliate; antheræ binate. See *Dianthera Debilis*.

38. *Justicia Violacea*. Shrubby: leaves lanceolate; spikes terminating; bractes lanceolate, imbricate, ciliate; antheræ binate. See *Dianthera Violacea*.

39. *Justicia Rohrii*. Herbaceous: leaves elliptic, quite entire; spikes terminating, compound, imbricate, pubescent; bractes ovate; antheræ binate; flowers opposite.—Native of Cayenne. See the first species.

40. *Justicia Polystachya*. Herbaceous: leaves lanceolate, ovate; spikes axillary, opposite, pointing one way; bractes ovate, hirsute; antheræ binate; flower solitary, sessile, in the axils of the bractes.—Native of Cayenne. See the first species.

41. *Justicia Refusa*. Herbaceous: leaves ovate, acuminate; spikes terminating; bractes obovate, subretuse, imbricate; antheræ binate; corolla large, purple, cloven beyond the middle; stamina the length of the upper lip.—Native of the island of Santa Cruz. See the first species.

42. *Justicia Flava*. Shrubby: leaves lanceolate, oblong; spikes terminating; flowers in pairs; bractes lanceolate blunt. See *Dianthera Flava*.

43. *Justicia Americana*. Herbaceous: leaves linear-lanceolate; spikes axillary, solitary, like corymbs; peduncles filiform, alternate, the length of the leaves; antheræ binate. See *Dianthera Americana*.

44. *Justicia Punctata*. Herbaceous: leaves lanceolate-ovate; spikes terminating; flowers remote, in a sort of whorl; bractes lanceolate, acuminate. See *Dianthera Punctata*.

45. *Justicia Eustachiana*. Shrubby: leaves oblong, acuminate; spikes axillary and terminating; flowers in remote whorls, two or three together, solitary at top; bractes wedge-shaped; flowers purple, inodorous.—Native of the West Indies, common on the open arid hills of St. Eustatia. See the first species.

46. *Justicia Pectoralis*. Herbaceous: leaves lanceolate, petioled; spikes panicled; bractes minute; upper lip undivided; antheræ binate; flowers numerous, red, sessile; the whole plant has the smell of new hay, mixed with a refreshing aromatic scent.—Native of St. Domingo and Martinico, where the inhabitants make a syrup of it, which they use in disorders of the breast. The bruised leaves are also good in wounds and cuts; and hence the French call this plant *Herbe à charpentiere*. See the first species.

47. *Justicia Comata*. Herbaceous: leaves linear-lanceolate, subsessile; spikes subumbelled, whorled; bractes minute; antheræ binate. See *Dianthera Comata*.

48. *Justicia Undulata*. Herbaceous: leaves lanceolate, waved; peduncles terminating, umbelled, simple, and trifid; antheræ binate; capsules villose.—Observed by Kœnig in Malabar. See the first species.

49. *Justicia Frondosa*. Herbaceous; umbels axillary, peduncled, compound; peduncles elongated; bractes ovate, rhombed, smooth, blunt; antheræ binate; stem round, smooth.—Native of Otaheite. See the first species.

50. *Justicia Pubescens*. Shrubby: peduncles axillary, opposite, four-flowered, pedicelled; bractes ovate-roundish, mucronate, pubescent; antheræ binate.—Native of Botany island. See the first species.

51. *Justicia Lævigata*. Shrubby: peduncles axillary, opposite, three-flowered, pedicelled; bractes oblong, mucronate, pubescent; antheræ binate; stem covered with an ash-coloured bark, except at top, where it is green.—Native of Java. See the first species.

52. *Justicia Cuspidata*. Peduncles axillary, in whorls, subtriflorous, pedicelled; bractes wedge-form, awned; antheræ binate. See the first species.

53. *Justicia Biflora*. Suffrutescent: peduncles axillary, two-flowered, pedicelled, equalling the leaves; bractes awl-shaped; antheræ binate; pedicels unequal.—Native of the East Indies. See the first species.

54. *Justicia Sessilis*. Shrubby: leaves ovate-acute, subserrate; flowers solitary, sessile; upper lip quite entire; flowers inodorous, purple.—Native of the West Indies, in the coppices and hedges of the island of St. Eustatia, where it is found flowering in August. See the first species.

55. *Justicia Nigricans*. Shrubby: leaves lanceolate-linear, blunt, blackish; spikes distich, terminating; stem upright, six feet high; corolla white, variegated with red.—Native of Cochinchina. See the first species.

56. *Justicia Tinctoria*. Herbaceous: leaves lanceolate, subrenate, pubescent; flowers axillary, heaped; corolla rose-coloured. The leaves dye cloth of a fine green colour.—Native of Cochinchina. See the first species.

**** *Corollas ringent.*

57. *Justicia Adhatoda*; *Malabar Nut*. Arboreous: leaves ovate-lanceolate, acuminate; spikes axillary, opposite; bractes ovate-elliptic, leafy; antheræ parallel; it rises with a strong woody stem to the height of twelve or fourteen feet, sending out many spreading branches; flowers on short spikes at the end of the branches; corolla white, with some dark spots. It flowers in July, but does not bear seeds in

England. It may be propagated by cuttings, which, if planted in pots during June or July, and plunged into a very moderate hot-bed, will take root. They must be screened from the sun, and will succeed the better for the exclusion of the external air. It may also be propagated by laying down the young branches, which will take root in the tubs or pots in one year; then the young plants should be put each into a separate pot, filled with soft loamy earth, and placed in the shade till they have taken new root, when they may be placed in a sheltered situation during the summer; but in winter they must be housed, and treated in the same way as Orange-trees, with only this difference, that they require more water.

58. *Justicia Betonica*. Shrubby: leaves elliptic; spikes terminating, elongated; bractes ovate-acuminate, membranaceous, netted, coloured; antheræ binate, appendicled.—Native of the East Indies. See the first species.

59. *Justicia Repens*. Herbaceous: leaves elliptic, subsessile; spikes axillary, and terminating, pointing one way, smooth; bractes ovate, membranaceous at the edge; antheræ binate, appendicled.—Native of Ceylon. See the first species.

60. *Justicia Pectinata*. Herbaceous: leaves oblong; spikes axillary, pointing one way, tomentose; bractes half lanceolate, distich; corolla minute, white, with a green upper lip.—Native of the East Indies. See the first species.

61. *Justicia Sanguinolenta*. Herbaceous: stem creeping; leaves oblong; peduncles axillary, solitary, one-flowered. The whole plant is of a blood-red colour, from whence it derives its trivial name.—Native of Ceylon. See the first species.

62. *Justicia Japonica*. Herbaceous: leaves ovate-oblong, acuminate; peduncles axillary, alternate, four or five flowered, pedicelled; bractes lanceolate-ciliate. See *Dianthera Japonica*.

63. *Justicia Trisulca*. Shrubby: leaves oblong, blunt; peduncles axillary, subtriflorous, opposite; flowers sessile; antheræ binate. This is a stiff shrub, with opposite, distorted, warted, round branches; corolla an inch and a half in diameter.—Native of Arabia Felix. See the first species.

64. *Justicia Hyssopifolia*; *Snap Tree*. Shrubby: leaves lanceolate, blunt; peduncles axillary, one or two-flowered; bractes shorter than the calix; calicine segments oblong; antheræ binate, appendicled; stem from three to four feet high; flowers white, with long calices; capsules oblong, when ripe throwing out their seeds, whence its name of Snap-tree.—Native of the Canary islands. It is propagated by cuttings during any of the summer months; they should be planted in pots filled with light loamy earth, plunged into a moderate hot-bed shaded from the sun, and now and then gently refreshed with water; they must not have much air admitted to them; in about two months the cuttings will have taken root, then they must be gradually inured to the open air, by placing them in a sheltered situation, where they may remain till autumn. If they take root early in the summer, separate them each into a small pot placed in the shade; but if it be late in the season before they have taken root, let them remain in the same pots till the following spring. In winter these plants must be placed in a warm green-house, or moderately warm stove, for they are impatient of cold and damp, and will not thrive in much warmth: they often require watering in winter, but it must be sparingly given.

65. *Justicia Orchioides*. Shrubby: leaves lanceolate, sessile; peduncles axillary, solitary, one-flowered; bractes shorter than the calix; antheræ binate, appendicled. This is a very stiff smooth shrub; it flowers in August and September.—Native of the Cape. See the first species.

66. *Justicia Madurensis*. Shrubby: leaves oblong, toothed; peduncles axillary, one-flowered; stem solid, round, smooth, whitish; bractes in pairs, deciduous; flowers few.—Native of Madura. See the first species.

67. *Justicia Cuneata*. Shrubby: leaves obovate, emarginate; flowers axillary, solitary, sessile; antheræ binate; corolla like that of the Snap-tree.—Native of the Cape of Good Hope. See the first species.

68. *Justicia Tranquebarensis*. Suffrutescent: leaves obovate, on hoary branches; flowers axillary, solitary, sessile; bractes remote, obcordate; antheræ binate, appendicled; stem round, red, covered with slender white soft hairs.—Found by Koenig in Tranquebar. See the first species.

69. *Justicia Odora*. Shrubby: branches smooth; leaves roundish; flowers axillary, solitary, sessile, opposite; stem ash-coloured.—Native of Arabia Felix, where they make wreaths of it to wear about their heads on festivals. It has little scent while green, but, when dried, smells like *Anthoxanthum*, or Vernal Grass. See the first species.

***** Corollas almost equal.

70. *Justicia Infundibuliformis*. Shrubby: leaves lanceolate-ovate, in fours; spikes terminating; branches round; corolla handsome, white, with a filiform tube.—Native of the East Indies. See the first species.

71. *Justicia Sinuata*. Shrubby: leaves linear, oblong, sinuate-pinnatifid; peduncles axillary, trifid; corollas salver-shaped; antheræ parallel.—Native of the Isle of Tanna in the South Seas. See the first species.

72. *Justicia Spinosa*. Shrubby: leaves ovate or obovate; spines axillary; lateral peduncles simple; corollas salver-shaped; antheræ parallel; stem five feet high, dividing into few, round, weak, pliant, leafy, very long branches; flowers inodorous, less than an inch long, purple.—Native of St. Domingo and Jamaica. See the twelfth species.

73. *Justicia Repanda*. Shrubby: leaves elliptic, repand; peduncles axillary, trifid; corollas salver-shaped; antheræ parallel.—Native of the isle of Tanna.

74. *Justicia Armata*. Shrubby, prickly: leaves oblong, emarginate, coriaceous, shining.—Native of Jamaica. See the first species.

75. *Justicia Acicularis*. Shrubby, diffused, spiny: spines bristle-shaped; flowers peduncled, axillary, solitary.—Native of Jamaica. See the first species.

76. *Justicia Reptans*. Stem herbaceous, creeping; leaves blunt; spikes terminating, undivided.—Native of St. Domingo. See the first species.

77. *Justicia Humifusa*. Stem herbaceous, decumbent; leaves ovate and cordate; spikes umbelled.—Native of Jamaica. See the first species.

78. *Justicia Nemorosa*. Stem herbaceous, four-cornered, somewhat upright; leaves ovate-lanceolate; spikes ovate.—Native of St. Domingo and Jamaica. See the first species.

79. *Justicia Fruticosa*. Shrubby: leaves ovate or ovate-lanceolate, hirsute, petioled; bractes cordate, acuminate; flowers in loose clusters, from the axils towards the end of the branches, of a pale red colour.—Discovered by Dr. Houstoun, at Campeachy. See the twelfth species, for its propagation, &c.

80. *Justicia Arborea*. Arboreous: leaves lanceolate-ovate, sessile, tomentose underneath; flowers in clustered terminating spikes; they are small and white.—Sent from Campeachy. For its propagation, &c. see the twelfth species.

Ivy. See *Hedera*.

Ivy, Ground. See *Glechoma*.

Ixia; a genus of the class Triandria, order Monogynia.—

GENERIC CHARACTER. *Calix*: spathe bivalve, inferior,

shorter than the corolla; valves oblong, permanent, the exterior wide, sheathing the interior. *Corolla*: one-petalled, regular, superior; tube filiform, gradually enlarged, straight; border regular, bell-shaped, six-parted; divisions oblong, obtuse, equal, spreading. *Stamina*: filamenta three; thread subulate, inserted into the tube near the orifice, shorter than the corolla; antheræ oblong, furrowed. *Pistil*: germen inferior, triangular; style simple, filiform, upright; stigmas three, filiform. *Pericarp*: capsule ovate, three-sided, obtuse, three-celled, three-valved. *Seeds*: several, roundish, smooth.

ESSENTIAL CHARACTER. *Corolla*: one-petalled, tubular; tube straight, filiform; border six-parted, bell-shaped, regular, or nearly so; stigmas three or six, simple.—Several of the plants of this genus will ripen their seeds in our climate, and may be propagated by sowing the seed in pots, and plunging them into a moderate hot-bed, which will bring up the plants much sooner than when they are sown in the full ground; when fit to remove, they should each be set in a small pot filled with light earth, and, if they are placed under a frame till they have taken good root, it will greatly forward their growth; afterwards they may be placed in the open air, in a sheltered situation, and may remain there till autumn, when they must be placed under a frame to screen them from the frost: in the spring the plants may be turned out of the pots and planted in a warm border, where they will endure the cold of common winters very well; but in severe frosts they are often killed, unless protected by tan, or some other covering; on this account, a few of the plants should be kept in pots, and sheltered under a frame or in a dry-stove in winter. They multiply very fast by offsets, so that when they are once obtained, there will be no occasion to raise them from seeds. Most of them will flower in the ensuing season, whereas those from seeds are three or four years before they flower. The stalks and leaves of these plants decaying to the root in autumn, the roots in borders should then be covered two or three inches thick with tan, to keep them from frost, and also from mice, who are very fond of them. The spring before the roots shoot, is the best time to remove and part them; but this should not be done oftener than every third year, for if often parted, they will not flower well.—The species are,

1. *Ixia Fruticosa*; *Shrubby Ixia*. Stem branched, covered with imbricate leaves; flowers terminating, blue; tube of the corolla yellow.—Native of the Cape of Good Hope, and of Terra del Fuego.

2. *Ixia Minuta*; *Minute Ixia*. Scapes one-flowered, shorter; leaves even; bulb globular, covered with a net, the size of a pea; tube of the corolla white, with purple streaks; antheræ upright, yellow.—Native of the Cape of Good Hope.

3. *Ixia Bulbocodium*; *Crocus-leaved Ixia*. Stem one-flowered; leaves linear, closely complicated; stigmas six; flower lateral, inodorous; corolla pale violet, yellow on both sides at the base. It flowers about the middle of April; but the blossoms do not fully expand unless exposed to the sun, nor are they of long duration. It affects dry hilly situations.—Native of Italy.

4. *Ixia Rosea*; *Rose-coloured Ixia*. Scapes one-flowered; leaves linear, nerved, incrassated at the edge; stigmas six; flowers at the ends of the branches, rather large, coming one after the other; tube of the corolla very short; segments of the border yellow within. It varies with the three inner segments of the corolla yellow, and the three outer green; the three inner white-yellow, the three outer greenish; the three inner blue-white, the three outer greenish; the three inner white, the three outer green; with corollas wholly yellow,

or wholly blue, or rose-coloured with a yellow base. It varies also in the size of the flowers.—Native of the Cape.

5. *Ixia Parviflora*; *Small-flowered Ixia*. Leaves linear, compressed; segments of the corolla lanceolate, reflex, the inner scarcely wider; stigmas bifid, spreading, revolute.—Gathered wild in Jersey by Mr. R. Finlay.

6. *Ixia Fugax*; *Fugacious Ixia*. Leaves linear, compressed; segments of the corolla linear-lanceolate, blunt, the inner wider and more erect; stigmas bifid, horizontal, recurved.—Native of the Cape of Good Hope.

7. *Ixia Humilis*; *Humble Ixia*. Scape branched; flowers pointing one way; leaves grooved, erect, longer. It varies with the corolla yellow, whitish, rufescent, or flesh-coloured; with an undivided few-flowered scape, and a branched many-flowered scape.—Native of the Cape of Good Hope.

8. *Ixia Pilosa*; *Hairy Ixia*. Leaves linear, hairy, shorter; flowers alternate, sessile, somewhat nodding; corolla rufescent without, white within. The flowers open from four in the afternoon.—Native of the Cape of Good Hope.

9. *Ixia Hirta*; *Rough-haired Ixia*. Leaves ensiform, rough-haired, shorter; flowers pointing one way, dark blue.—Native of the Cape of Good Hope.

10. *Ixia Secunda*; *One-ranked Ixia*. Leaves elliptic, ensiform, shorter; scape villose, rugged; flowers generally from five or six, upright, blue. It varies with the scape simple and branched.—Native of the Cape of Good Hope.

11. *Ixia Crispa*; *Wave-leaved Ixia*. Leaves linear, waved, shorter; flowers alternate; tube of the corolla greenish; segments of the border blue: it varies with the scape simple and branched, and with the corollas blue and white.—Native of the Cape of Good Hope.

12. *Ixia Cinnamomea*; *Cinnamon-coloured Ixia*. Leaves lanceolate, waved, shorter; flowers alternate; bulb conical; tube of the corolla a little enlarged, and somewhat curved, purplish. The three inner segments of the border entirely white; the three outer white within, purple, striated without.—Native of the Cape of Good Hope.

13. *Ixia Corymbosa*; *Corymbed Ixia*. Leaves lanceolate, waved, shorter; scape ancipital. It varies with white and blue flowers.—Native of the Cape of Good Hope.

14. *Ixia Linearis*; *Linear-leaved Ixia*. Leaves linear, shorter; scape simple, upright; bulb ovate, fibrous, even, the size of a hazel nut; flowers terminating the branches, at the end of the scape.—Native of the Cape of Good Hope.

15. *Ixia Capillaris*; *Slender-scaped Ixia*. Leaves linear, shorter; scape branched; spathe scarious; bulb netted, fibrous, the size of a hazel nut; tube of the corolla whitish.—Native of the Cape of Good Hope.

16. *Ixia Setacea*; *Bristle-leaved Ixia*. Leaves linear, shorter; scape flexuose, smooth: the three outer segments of the border of the corolla are white within, red-streaked without; the three inner entirely white. It varies with a greenish corolla, white at the tips, and with a yellow corolla, with the base of the border dusky; with the scape one-flowered, many-flowered and simple, many-flowered and branched.—Native of the Cape of Good Hope.

17. *Ixia Scillaris*; *Squill-flowered Ixia*. Leaves linear, shorter; flowers pointing one way; rachis flexuose; scape round, upright, smooth.—Native of the Cape of Good Hope.

18. *Ixia Aulica*; *Cluster-flowered Ixia*. Flowers in racemes; bractes entire; leaves ensiform, flat, nerved, even. It flowers in April.—Native of the Cape of Good Hope.

19. *Ixia Bulbifera*; *Bulb-bearing Ixia*. Leaves ensiform, shorter; spathes membranaceous, bristle-shaped, jagged; flowers three or more, large, with the rachis between the flowers flexuose. It varies with the corolla purple, red,

white, and yellow, with the scape very short and simple, higher and branched, and bulbiferous.—Native of the Cape.

20. *Ixia Aristata*; *Bearded Ixia*. Leaves ensiform, smooth; flowers alternate, sessile; spathes the length of the tube, and jagged; bulb netted, the size of a hazel-nut; scape simple, round, upright, smooth, from a hand to a foot in height, or more; corollas white, flesh-coloured. It varies with whitish corollas, having a purple star, violet-coloured, and yellow.—Native of the Cape of Good Hope.

21. *Ixia Reticularis*; *Netted Ixia*. Border of the corolla four times as long as the tube, recurved, funnel-form at the base; segments spatulate, somewhat acuminate, the inner narrower; filamenta erect; stigmas at the base of the antheræ.—Native of the Cape of Good Hope.

22. *Ixia Villosa*; *Dark-red Ixia*. Leaves oblong, lanceolate-acute, villose, somewhat plaited, distich; tube equal to the spathe; flowers alternate, sessile, upright, often three.—Native of the Cape of Good Hope.

23. *Ixia Pendula*; *Pendulous-flowered Ixia*. Leaves linear, ensiform, shorter; scape branched; spikes pendulous; root jointed like a necklace; corollas on the branches alternate, large, flesh-coloured, with a short tube. This is the loftiest of the genus, and the large pendulous corollas are very handsome.—Native of the Cape of Good Hope. It is well worth the trouble of cultivating.

24. *Ixia Flexuosa*; *Bending-stalked Ixia*. Leaves linear; raceme flexuose, many-flowered; bulb very small, round; stem very slender, round, a foot and half high. The corolla is pure white, and small.—Native of the Cape.

25. *Ixia Polystachia*; *Many-spiked Ixia*. Leaves ensiform, shorter; scape branched; flowers alternate, unspotted; border of the corolla incurved, and spreading very much; segments lanceolate, blunt, equal in breadth; filamenta spreading and recurved; stigmas at the base of the filamenta; bulb the size of a hazel-nut; scape round, smooth, upright, two feet high. It varies with the corollas yellow and violet, of one colour. Native of the Cape of Good Hope.

26. *Ixia Longiflora*; *Long-flowered Ixia*. Leaves ensiform, linear, stiff; tube filiform, very long; scape four or five spans high, the thickness of a rye-straw, upright, round, even, yellowish, naked at top, and branched; flowers in spikes, yellow. They appear from April to June.—Native of the Cape of Good Hope.

27. *Ixia Plantaginea*; *Fox-tail Ixia*. Leaves linear, stiff; spike distich, imbricated; root consisting of several little bulbs; flowers very small. It varies with the corollas white and blue.—Native of the Cape of Good Hope.

28. *Ixia Marginata*; *Broad-leaved Ixia*. Many-spiked; leaves ensiform, nerved, thicker at the edge; spikes pressed close; tube curved inwards; stigmas six; flowers large, pendulous.—Native of the Cape of Good Hope.

29. *Ixia Patens*; *Spreading-flowered Ixia*. Leaves ensiform, smooth; raceme terminating; corolla bell-shaped, patulous, alternate; segments narrower; filamenta upright; stigmas above the base of the antheræ; bulb flattened. It flowers in April.—Native of the Cape of Good Hope.

30. *Ixia Maculata*; *Spotted Ixia*. Leaves ensiform, shorter; scape branched; flowers alternate; corollas spotted at the base; bulb double the size of a hazel-nut; stalk slender, stiff, a foot and half long, naked to the top, where it is terminated by a round bunch of flowers, on short peduncles of a deep yellow colour, with a dark purple bottom.—Native of the Cape of Good Hope.

31. *Ixia Deusta*; *Copper-coloured Ixia*. Leaves lanceolate, nerved; flowers alternate, sessile; tube shorter than the bractes; borders blunt, the outer spotted at the base, and

keeled; stigmas under the middle of the antheræ. Mr. Salisbury changes the name from *Deusta* to *Gibba*, choosing to denominate it from the form rather than the colour of the flower. It flowers in May.—Native of the Cape of Good Hope.

32. *Ixia Crocata*; *Crocus-flowered Ixia*. Leaves ensiform; flowers alternate; tube the length of the bractes; borders of the corolla ovate, quite entire, hyaline at the base; stigmas at the tip of the antheræ. The flowers are handsome, they point one way, are bell-shaped, with a short orange-coloured tube, with a paler hyaline or transparent mark above the mouth of the tube. This is one of the handsomest of the genus, and, like all the rest, becomes handsomer and more branched by cultivation.—Native of the Cape of Good Hope.

33. *Ixia Squalida*; *Squalid Ixia*. Leaves linear-lanceolate; flowers alternate, sessile; tube longer than the bractes; borders ovate-oblong; stigmas below the tip of the antheræ. It strongly resembles the preceding, and flowers in May.—Native of the Cape of Good Hope.

34. *Ixia Lancea*. Leaves ensiform, shorter; flowers pointing one way; scape simple, flexuose; flowers about six, purplish white.—Native of the Cape.

35. *Ixia Pentandra*. Leaves ensiform, shorter; flowers five-stamined; scape branched or simple, round, flexuose, smooth, a foot high; spike of flowers long, interrupted, flexuose; tube of the corolla greenish, short; segments of the border purple.—Native of the Cape of Good Hope.

36. *Ixia Falcata*. Leaves ensiform, reflex, sickle-shaped, shorter; bulb conical, imbricate downwards, truncated, with a sharp fibrose margin, the size of a pea; flowers alternate, one or more; tube of the corolla red. It varies with the scape simple or branched, a hand or a span in height; with flowers alternate, or pointing one way.—Native of the Cape.

37. *Ixia Excisa*. Leaves ovate, shorter; flowers pointing one way; scape flexuose; bulb globular, smooth, less than a pea; scape round, upright, smooth, one-flowered or many-flowered, a finger or a hand in length; tube of the corolla red.—Native of the Cape of Good Hope.

38. *Ixia Chinensis*; *Chinese Ixia*. Leaves ensiform; panicle dichotomous; flowers peduncled; scape round, fistulous, jointed, upright, simple at bottom; corolla connected only by the base, yellow and purple, spotted. The Indians consider this plant as an antidote to poisons in general, and regard the bruised root as peculiarly efficacious in curing the bite of the serpent called Cobra de Capello.—Native of the East Indies, China, Cochinchina, and Japan. The stalks are seldom more than three feet high in our climate.

39. *Ixia Pallax*. Border of the corolla incurved, and spreading very much; segments oval, slightly emarginate, equal in breadth; filamenta spreading, and recurved; stigmas as at the base of the filamenta; corolla violet-coloured.—Native of the Cape of Good Hope.

40. *Ixia Mutabilis*. Border of the corolla reflex, salver-shaped at the base; segments broadly obovate, retuse, the inner narrower; filamenta from upright spreading; stigmas below the apex of the tube; border of the corolla one and one-third longer than the tube.—Native of the Cape.

41. *Ixia Socialis*. Border of the corolla horizontal; segments elliptical, the outer emarginate, the inner narrower, blunt; filamenta from upright spreading; stigmas at the middle of the filamenta; border of the corolla four-sevenths longer than the tube; corolla white, with a green base.—Native of the Cape of Good Hope.

42. *Ixia Lineata*. Border of the corolla incurved, and spreading very much; segments oval, blunt, inner narrower; filamenta recurved at the tip; stigmas below the tip of the filamenta; border of the corolla one and a half longer than

the tube; herb bright green, smooth, rigid.—Native of the Cape of Good Hope.

43. *Ixia Amœna*. Border of the corolla incurved and horizontal; segments oval-lanceolate, somewhat retuse, inner narrower; filamenta from upright spreading; stigmas at the base of the filamenta; corolla rose-purple-coloured, with a deep purple base; limb longer by half than the tube.—Native of the Cape of Good Hope.

44. *Ixia Retusa*. Border of the corolla incurved, and spreading very much; segments oval, retuse, inner narrower; filamenta upright; stigmas at the middle of the filamenta.—Native of the Cape of Good Hope.

45. *Ixia Spectabilis*. Border of the corolla incurved and horizontal; segments lanceolate, outer emarginate, inner narrower, blunt; filamenta from upright spreading; stigmas at the base of the filamenta; flowers peduncled, and forming a dense pyramidal spike; border of the corolla three times longer than the tube, deeply six-parted, green or blue-green, with a dark purple base. It flowers from May to August.—Native of the Cape of Good Hope.

46. *Ixia Concolor*. Border of the corolla incurved, and horizontal; segments elliptical, blunt, inner narrower; filamenta from upright spreading; stigmas above the middle of the antheræ; limb of the corolla five times longer than the tube; corolla deep red.—Native of the Cape of Good Hope.

47. *Ixia Conica*. Border of the corolla reflex, shaped like a dish at the base; segments elliptical, blunt, inner broader; filamenta upright; stigmas above the base of the antheræ; corolla vermilion-coloured, with a variegated star at the base; limb twice as long as the tube.—Native of the Cape.

48. *Ixia Conspicua*. Border of the corolla incurved and horizontal; segments elliptical, blunt, inner narrower; filamenta from upright recurved; stigmas at the base of the filamenta; corolla orange-coloured, with a dark base; limb one-third longer than the tube.—Native of the Cape.

49. *Ixia Concinna*. Border of the corolla reclining, funnel-form at the base; segments elliptical, blunt, inner narrower; filamenta from upright recurved; stigmas below the middle of the filamenta; corolla pale yellow; limb longer by half than the tube.—Native of the Cape of Good Hope.

50. *Ixia Columnaris*. Border of the corolla the length of the tube, reflex, salver-shaped at the base; segments elliptical, the inner a little wider; filamenta monadelphous; stigmas above the base of the antheræ; limb of the corolla the same length as the tube. Native of the Cape of Good Hope.

51. *Ixia Erosa*. Margins of the nerves duplicate-ciliate; base of the corolla funnel-form; segments elliptical, gnawn at the tip. This species is singular in its almost total want of a tube, but in other respects it has the characters of this genus.—Native of the Cape of Good Hope.

52. *Ixia Tardiflora*. Border of the corolla recurved at top; segments broadly spatulate-emarginate, the three lower at the disk of the base within, putting out a little keel; stigmas at the base of the antheræ. The limb of the corolla is six times longer than the tube. It has its name from its flowering very slowly in our stoves.—Native of the Cape.

53. *Ixia Propinqua*. Border of the corolla recurved and spreading at top; segments spatulate, slightly emarginate, the three lower approximating a little at the disk of the base within, putting out a little keel; stigmas at the middle of the antheræ; limb of the corolla three and a half longer than the tube.—Native of the Cape of Good Hope.

54. *Ixia Ambigua*. Border of the corolla recurved a little at top; segments rhomb-spatulate, equal in breadth, the outer somewhat gibbous at bottom, emarginate, inner blunt; stigmas above the middle of the antheræ; limb of the corolla

three and a half longer than the tube. The roots of this, and indeed of almost all the plants of this genus, are frequently eaten by the inhabitants of the Cape of Good Hope, where it is a native.

Ixora: a genus of the class Tetrandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth four-parted, very small, upright, permanent. *Corolla*: one-petalled, funnel-form; tube cylindric, very long, slender; border four-parted, flat; divisions ovate. *Stamina*: filamenta four, above the mouth of the corolla, very short; antheræ oblong. *Pistil*: germen roundish, inferior; style filiform, length of the tube; stigma two-cleft. *Pericarp*: berry roundish, two-celled. *Seeds*: by fours, convex on one side, cornered on the other. *Observe*. Gærtner says the seeds are solitary! partition perforated through the middle. ESSENTIAL CHARACTER. *Corolla*: one-petalled, funnel-form, long, superior. *Stamina*: above the mouth. *Berry*: four-seeded. Gærtner says, *Seeds* solitary, with a fleshy soft albumen. The plants of this genus are propagated from seeds, when the seed can be procured from their native countries; for they do not perfect seeds in England. They should be sown as soon as they arrive, in small pots, and plunged into a hot-bed: if they arrive in autumn or winter, the pots may be plunged in the tan-bed in the stove, between the pots of other plants, where they will take up little room: but when they arrive in the spring, it will be best to plunge them into a tan-bed under frames. The seeds when fresh will sometimes come up in about six weeks; when not fresh they often lie four or five months; and sometimes even a whole year, in the ground. On this account the earth should not be thrown out of the pots till there is no hope of their growing. When they come up, and are fit to remove, they should be each placed in a separate small pot, filled with light earth, and afterwards treated in the manner directed for the Coffee Tree. They may also be increased by cuttings during the summer months. The cuttings should be planted in small pots, plunged into a moderate hot-bed, covering them close with bell or hand-glasses, to exclude the external air, and shading them carefully from the sun in the heat of the day, until they have put out good roots; when they should be parted, and each put into a separate pot, treating them as the seeding plants. Mr. Curtis remarks,

that, though we have been accustomed to treat the *Ixoræ* as stove-plants, they may perhaps be more hardy than we suspect.—The species are,

1. *Ixora Coccinea*; *Scarlet Ixora*. Leaves oval, half stem-clasping; flowers in bundles; stem woody, five or six feet high, sending out many slender branches, covered with a brown bark; colour of the flowers scarlet; corolla salver-shaped.—Native of the East Indies, China, and Cochin-china.

2. *Ixora Alba*; *White Ixora*. Leaves lanceolate-ovate; flowers in bundles; they terminate in small clusters, have long slender tubes, divided into four segments at top, and are white and scentless; stem woody, six or seven feet high, sending out weak branches.—Native of the East Indies and Cochin-china.

3. *Ixora Americana*; *American Ixora*. Leaves in threes, lanceolate-ovate; flowers thyrsoid. They appear at the ends of the branches in a loose spike, are white, and have a scent like Jasmin; whence, in Jamaica, and other islands of the West Indies, where it is a native, it is called Wild Jasmin. It rises with a shrubby stalk four or five feet high, sending out slender branches, opposite.

4. *Ixora Fasciculata*. Leaves ovate, elliptic, those of the branchlets subfascicled; peduncles subtriflorous.—Native of Jamaica.

5. *Ixora Multiflora*. Leaves lanceolate-ovate, bundled; peduncles aggregate, one-flowered, very short; berries one-seeded.—Native of Jamaica.

6. *Ixora Montana*. Leaves turbinate-oblong, cordate at the base; flowers fastigate; stem shrubby, upright, branched, four feet high; flowers terminating, scarlet. Perhaps a variety of the first species.—Native of Cochin-china.

7. *Ixora Novemnervia*. Stem scandent; leaves nerved, rough; cymes terminating. This is a large, climbing, branched, unarmed shrub; flowers white; stamina above the throat; stigma ovate, bifid.—Native of Cochin-china.

8. *Ixora Violacea*. Leaves nerved, hairy; flowers axillary; they are violet-coloured. This also is a large climbing, branching, unarmed shrub.—Native of Cochin-china.

9. *Ixora Parviflora*. Leaves subsessile, lanceolate-oblong; panicle terminating; branches smooth, jointed, round at bottom, but compressed at top; flowers scarlet, some say white.—Native of the East Indies.

K Æ

KÆMPFERIA; a genus of the class Monandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth superior, obscure. *Corolla*: one-petalled; tube long, slender; border flat, six-parted: the three alternate divisions lanceolate, equal; the other two divisions ovate; the upper one two-parted, the divisions obcordate: all equal in length. *Stamina*: filamentum one, membranaceous, subovate, emarginate; antheræ linear, doubled, entirely adnate, scarce emerging from the tube of the corolla. *Pistil*: germen roundish; style the length of the tube; stigma two-plated, roundish. *Pericarp*: capsule roundish, three-sided, three-celled, three-valved. *Seeds*: several. *Observe*. It rarely bears fruit: the germen is seated near the root. ESSENTIAL CHARACTER. *Corolla*: six-parted, three of the parts larger, spreading, one or two-parted; stigma two-plated.—The species are,

1. *Kæmpferia Galanga*; *Galangale*. Leaves ovate, sessile; segments of the corolla lanceolate-linear. It is an annual, stemless, juicy plant; root bulbous. The smell of all

K Æ

its parts is aromatic, pleasant, and permanent; the taste is sharpish; the colour of the root white within, purple on the outside. An infusion of the roots, which are kept by the druggists, in boiling water, or a tincture made with brandy, is a good medicine in windy complaints, and other disorders of the stomach, as well as for head-aches, which arise in general more from debility than any other cause.—Native of the East Indies. This and the next species being natives of hot countries, will not bear the open air in England, and require a warm stove to preserve them through the winter: but as their leaves decay in the autumn, the plants should not have too much wet while they remain in an inactive state. If they are placed in the bark-stove, and treated in the same manner as is directed for the Ginger, they will thrive and produce plenty of flowers every summer. They are both propagated by parting their roots; the best time for which is in the spring, before they put out their leaves.

2. *Kæmpferia Rotunda*. Leaves lanceolate, petioled; segments of the corolla linear. The roots are shorter than the

above, growing in large clusters, covered with an ash-coloured skin, white within. The flowers rise from the root, are of mixed colours, blue, purple, white, red, with a fragrant odour.—Native of the East Indies. See the preceding species.

Kale. See *Brassica Oleracea*.

Kalmia; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, small, permanent; segments imbricate, acute, rather columnar. *Corolla*: one-petalled, salver-funnel-form; tube cylindric, longer than the calix; border with a flat disk, the margin upright, half five-cleft, ten nectariferous hornlets projecting outwardly from the corolla, and surrounding it where the border of it is upright. *Stamina*: filamenta ten, awl-shaped, upright, spreading, rather shorter than the corolla, inserted into the base of the corolla; antheræ simple. *Pistil*: germen roundish; style thread-form, longer than the corolla, bent down; stigma obtuse. *Pericarp*: capsule subglobose, depressed, five-celled, five-valved, five-partite. *Seeds*: numerous. *Observe*. The horned nectaries projecting outwardly from the corolla, and surrounding it, sufficiently distinguish this genus from the Bicornes. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: salver-form, with the border five-horned beneath. *Capsule*: five-celled.—The species are,

1. *Kalmia Latifolia*; *Broad-leaved Kalmia*. Leaves ovate-elliptic, by threes, and scattered; corymbs terminating. This shrub in its native soil continues flowering great part of the summer, and is one of the greatest ornaments of the country. The noxious qualities of this elegant shrub, greatly derogate from its peculiar beauty. Though deer feed on its green leaves with impunity, yet in severe winters, when cattle and sheep are obliged to feed on it alone, great numbers of them die. The stem rises to the height of ten or twelve feet, and is sometimes as large as the small of a man's leg. The flowers burst out from their empalements in June, forming a round bunch or corymbus, sitting very close to the branch. They are of a pale blush colour, the inside of the petal of a peach colour. The wood is like that of Box, very close-grained, heavy, and hard, very useful in small works. The Indians are said to make dishes, spoons, and other domestic utensils, out of the roots, which are large, of a soft texture, and easily wrought while green, but when dry becoming hard and smooth.—Native of Carolina, Virginia, and other parts of North America, where it is generally found upon rocks, hanging over rivulets, and on the sides of barren hills, in most sterile soils. They multiply there by their creeping roots, and here by throwing up suckers, if not removed. The seeds seldom ripen in England, and those sent from America lie in the ground a whole year before the plants appear, and afterwards make very little progress. The plants that come up from suckers are most likely to produce others and flower much sooner. They succeed best in a northern aspect, well-sheltered, in a moderately moist situation, upon loam and bog-earth, and in a pure air. As this species is difficult to propagate by suckers or layers, it is generally raised from American seeds.

2. *Kalmia Angustifolia*; *Narrow-leaved Kalmia*. Leaves lanceolate; corymbs lateral; stems from three to six feet high, dividing into small woody branches; flowers in loose bunches, on the side of the branches, upon slender peduncles: they are bright red when they first open, but afterwards fade to a blush or peach-bloom colour. The varieties with pale and deep red flowers, differ in their habit: the latter, the most humble of the two, not only produces the most brilliant flowers, but in greater abundance.—It is a native of North America, and is reputed poisonous to sheep and cattle. It

is extremely hardy, thrives best in bog-earth, and is generally propagated by layers. See the first species.

3. *Kalmia Glauca*; *Glaucous Kalmia*. Leaves opposite, oblong, levigated, glaucous underneath, revolute; corymbs terminating; branchlets ancipital. It flowers in April and May, rarely exceeds two feet high, and is a native of Newfoundland. For its propagation and culture, see the first species.

4. *Kalmia Hirsuta*. Leaves ovate, attenuated to both ends; peduncles axillary, one-flowered; flowers purple-coloured. It can hardly be kept alive in this country by the most careful management.—Native of Carolina, North America.

5. *Kalmia Cuneata*. Leaves scattered, sessile, cuneate-oblong, pubescent underneath, slightly aristated at the extremity; corymbs lateral, with few flowers, which are white, with red at the bottom.—Native of the mountains of Carolina.

Kidney-Bean. See *Phaseolus*.

Kidney-Bean Tree. See *Glycine*.

Kidney-Vetch. See *Anthyllis*.

Kidney-Wort. See *Saxifraga*.

Kiggelaria; a genus of the class Diccia, order Decandria.—GENERIC CHARACTER. *Male*. *Calix*: perianth one-leaved, five-parted, concave; divisions lanceolate, concave. *Corolla*: petals five, lanceolate, concave, rather longer than the calix, and forming with it a pitcher-shaped figure. *Nectary*: glandules obtusely three-lobed, middle lobe largest, depressed, coloured, each growing to the claw of each petal. *Stamina*: filamenta ten, very small; antheræ oblong, shorter than the calix, gaping at the tips, with two holes. *Female*. *Calix*: as in the male. *Corolla*: as in the male. *Pistil*: germen roundish; styles five, simple; stigmas obtuse. *Pericarp*: capsule leathery, globose, rough, one-celled, five-valved. *Seeds*: about eight, roundish, cornered on one side, covered by a proper coat. ESSENTIAL CHARACTER. *Male*. *Calix*: five-parted. *Corolla*: five-petalled; glands five, three-lobed; antheræ perforated at the tip. *Female*. *Calix* and *Corolla* as in the male. *Styles*: five. *Capsule*: one-celled, five-valved, many-seeded.—The only known species is,

1. *Kiggelaria Africana*. This is a tree, exceeding the height of a man, with the trunk and branches gray; leaves alternate, lanceolate, petioled, smooth, stiff, and straight, sharply serrate, acute, spreading. On the male plant one or two branched peduncles bear several flowers, nodding in a panicle; the petals are white, and the nectaries yellow. The female produces a single flower on a simple peduncle.—Native of the Cape of Good Hope. It will not live in the open air of our climate, and therefore cannot grow very large. They are very difficult to propagate except by seeds, which are seldom ripened in England. The best time to plant the cuttings is in the spring, just before the plants begin to shoot: they should be placed in pots of soft loamy earth, and plunged into a very moderate hot-bed, covering them close with a glass to exclude the air. They must be shaded from the sun, and have very little water after their first planting. If any of them grow, remove them into separate small pots filled with loamy earth, and expose them to the air in a sheltered situation till autumn, when they must be removed into the green-house, and treated in the same manner as Orange-trees.

King's-Spear. See *Asphodelus*.

Kleinhovia; a genus of the class Gynandria, order Decandria, according to Linneus; but Schreber classes it under Dodecandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets oblong, nearly equal, the lower one rather shorter, deciduous. *Corolla*: petals five, lanceolate, sessile, rather longer than the calix; the

upper one shorter, wider, and arch-truncated; nectary central, seated on a column of the length of the calix, surrounded at the base by glandules, ascending at the tip, bell-shaped, very small, half five-cleft; divisions recurved. *Stamina*: filamenta fifteen, very small, three of them sitting on each division of the nectary, two of them being terminal, the third rather lower; antheræ twin. *Pistil*: germen in the hollow of the nectary, ovate, five-cornered; style simple; stigma somewhat crenated. *Pericarp*: capsule five-lobed, five-cornered, ten-valved, inflated. *Seeds*: solitary, roundish, subechinated. *Observe*. It is allied to *Ayenia*, but very distinct from it. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Corolla*: five-petalled. *Nectary*: bell-shaped, peduncled, stamiferous. *Capsule*: inflated, five-lobed.—The only known species is,

1. *Kleinovia Hospita*. Leaves alternately scattered, longer than the petioles; flowers in racemes, small, numerous, bright purple; trunk the height of a common apple-tree, thick, incurved, and knobbed. The whole plant is smooth, its leaves when bruised, especially the young ones, smell like violets.—Native of Java, Amboyna, and the Philippine Islands, where it flowers frequently in the year, and has commonly fruit on it, but most abundantly in October.

Knapweed. See *Centaurea*.

Knautia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth common, containing the floscules disposed in a simple orb, simple, cylindric, oblong, upright; divisions awl-shaped, approximated, of the number of the floscules; perianth proper, very small, crowning the germen, quite entire, coriaceous, pervious at top. *Corolla*: universal equal; proper one-petalled, unequal; tube the length of the calix; border unequal, four-cleft, the exterior segment larger, ovate. *Stamina*: filamenta four, longer than the tube of the corolla, inserted into the receptacle; antheræ oblong, incumbent. *Pistil*: germen inferior; style filiform, length of the stamina; stigma thickish, two-cleft. *Pericarp*: none. *Seeds*: solitary, four-sided, crowned with the down, and covered with the proper involucre of the flower; receptacle common, scarcely remarkable, flat, naked. *Observe*. This genus is distinguished from *Scabiosa* by the tubulated calix, and the simple orbit of flowers. **ESSENTIAL CHARACTER.** *Calix*: common oblong, simple, five to ten-flowered; proper simple, superior; corollets irregular. *Receptacle*: naked.—The species are,

1. *Knautia Orientalis*. Leaves gashed; corollets in fives, longer than the calix. It rises with an upright branching stalk, four feet high; the branches terminated by single peduncles, each supporting one flower, with the florets of a bright red colour. It is annual, and a native of the Levant.—This, and the other species also, are easily propagated. If the seeds be permitted to scatter in the autumn, the plants will come up soon after; and if some of them be planted in the borders of the pleasure-garden, or among low shrubs near the walks in October, the plants will survive the winter, and flower in June. Their seeds will ripen at the end of July, or the beginning of August; and those who wish to gather them, must observe that they fall as soon as they are ripe. The only care these plants require, is to keep them free from weeds.

2. *Knautia Propontica*. Upper leaves lanceolate, quite entire; corollets in tens, equal to the calix; stem biennial, the thickness of a finger, two feet high, villose.—Observed by Forskal in the Levant. See the preceding species.

3. *Knautia Palæstina*. Leaves entire, six-leaved; seeds pappose; stem upright, straight, round, brachiate, some-

what hairy, scarcely a foot high. It is an annual plant.—Native of Palestine. See the first species.

4. *Knautia Plumosa*. Upper leaves pinnate; calices ten-leaved; seeds pappose; stem upright, straight, round, brachiate, pubescent, a foot and a half high; corolla pale blue.—Native of the Levant. See the first species.

Knawell. See *Sceleranthus*.

Knee Holly.

Knee Holm. } See *Ruscus*.

Knee Hulm. }

Knot-Grass. See *Illecebrum Verticillatum*, and *Polygonum Maritimum*.

Knoxia; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, superior, small, deciduous; leaflets sharp-pointed, one lanceolate, thrice the size of the rest. *Corolla*: one-petalled, funnel-form; tube filiform, long; border four-parted; divisions equal, somewhat oblong, rounded. *Stamina*: filamenta four, capillary, within the mouth of the corolla, antheræ oblong, equal. *Pistil*: germen roundish, inferior; style filiform, length of the stamina; stigmas two-headed. *Pericarp*: fruit naked, subglobose, sharp-pointed, furrowed. *Seeds*: two, roundish, sharp-pointed, outwardly convex, marked with three streaks; inwardly flat, connected at the upper part to a thread-form receptacle. **ESSENTIAL CHARACTER.** *Corolla*: one-petalled, funnel-form. *Seeds*: two, grooved. *Calix*: one leaflet larger.—The only known species is,

1. *Knoxia Zeylanica*. This plant has the appearance of a *Plumbago*, or a *Lychnis*. Stem upright, a foot high, smooth, jointed; leaves opposite, lanceolate, subsessile, veinless, smooth; spikes long, narrow, with scattered sessile flowers.—Native of Ceylon and of the East Indies.

Koelreuteria; a genus of the class Polygamia, order Monœcia.—**GENERIC CHARACTER.** *Hermaphrodite Flowers*. *Calix*: perianth five-leaved, inferior; leaflets ovate, blunt, concave, membranaceous, unequal, ascending towards the upper side, gaping below. *Corolla*: petals four, equal, ascending towards the upper side, the two lower opposite; claws roundish, upright, the length of the calix; borders lanceolate, recurved at the tip, spreading. *Nectary*: scalelets four, upright, two-parted, fastened to the claws of the petals, forming a crown at the opening. *Glands*: three, between the stamina and pistillum. *Stamina*: filamenta eight, awl-shaped, upright, fixed to a columnar receptacle; antheræ oblong, blunt. *Pistil*: germen oblong, three-sided, placed on the columnar receptacle; style simple, three-cornered, ascending, the length of the petals; stigma trifid, spreading, small. *Pericarp*: capsule oblong, three-celled, placed on the column. *Seeds*: in pairs. *Males*: superior. *Calix*, *Corolla*, and *Stamina*, as in the hermaphrodite. **ESSENTIAL CHARACTER.** *Calix*: five-leaved. *Petals*: four. *Nectary*: double, four scalelets, and three glands. *Stamina*: eight, fixed to a column. *Germen*: three-sided, fixed to the same column.—The only known species is,

1. *Koelreuteria Paullinioides*. Leaves equally pinnate, with six pairs of leaflets, which are ovate, lacinate, serrate, acute, smooth, flat.—It is a polygamous tree, and a native of China.

Kœnigia; a genus of the class Triandria, order Trigynia.—**GENERIC CHARACTER.** *Calix*: perianth three-leaved; leaflets ovate, concave, permanent. *Corolla*: none. *Stamina*: filamenta three, capillary, shorter than the calix; antheræ roundish. *Pistil*: germen ovate; styles none; stigmas three, often only two, approximated, villose, coloured. *Pericarp*: none; but the calix protects the seeds without

entirely covering it. *Seeds*: single, ovate, naked, length of the calix, terminated by the permanent stigmas. **ESSENTIAL CHARACTER.** *Calix*: three-leaved. *Corolla*: none. *Seed*: one, ovate, naked.—The only known species is,

1. *Koenigia Islandica*. Stem a finger's length, somewhat succulent, with very few branches opposite to the leaves, and spreading very much.—Native of Iceland, where it was found by Koenig, (after whom it has been named,) in overflowed clayey soils, both on the mountains and the coast.

Krameria; a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none, except the corolla be so termed. *Corolla*: petals four, equal, spreading, oblong, acute; the uppermost wider, the lateral ones ovate. *Nectaries*: two, the upper superior, erect, linear, three-parted; divisions linear, thickish, ovate at the tips, membranaceous, the lower inferior, two-leaved; leaflets linear, convex, clavated, wrinkled. *Stamina*: filamenta four, within the nectary, ascending; antheræ small, with two foramina at the tip. *Pistil*: germen ovate; style awl-shaped, ascending, length of the stamina; stigma acute. *Pericarp*: berry dry, globose, unilocular, echinated on all sides with stiff hairs directed backwards. *Seed*: single, ovate, smooth, hard. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: four-petalled. *Nectary*: upper three-parted, lower two-leaved. *Berry*: dry, echinated, one-seeded.—The only species yet discovered is,

1. *Krameria Ixina*. A shrub with alternate lanceolate leaves; flowers alternate, in terminating racemes.—Found in South America.

Kuhnia; a genus (according to Gærtner,) of the class Syngenesia, order Polygamia Æqualis, which Linneus had classed in Pentandria Monogynia. *Calix*: perianth common oblong, imbricated; scales very many, unequal, lanceolate, gibbose, permanent. *Corolla*: common equal; floscules from ten to fifteen; corolleis one-petalled, funnel-form, twice the length of the calix; border five-cleft, upright. *Stamina*: filamenta five, capillary, very short; antheræ subcylindric, shorter than the tube of the corollet, gaping, with a lip at the top. *Pistil*: germen inferior; style the length of the stamina; stigmas two, clubbed. *Pericarp*: calix unchanged. *Seeds*: solitary, oblong, columnar, striated, smooth, crowned with a feathery down, longer than the calix or seed. *Receptacle*: naked, scrobicular, somewhat rugged. *Observe.* The compound flower is allied to *Eupatorium*, but the antheræ are very dissimilar, though Gærtner declares that they are by no means separate, or even separable, without force. **ESSENTIAL CHARACTER.** *Flowers*: floscular. *Calix*: imbricate, oblong, cylindrical. *Down*: plumose. *Receptacle*: naked. *Style*: deeply bifid. *Stigmas*: club-shaped; antheræ distinct.—The species are,

1. *Kuhnia Eupatorioides*. Leaves alternate, petioled, broad-lanceolate, naked, somewhat wrinkled, veined underneath, somewhat toothed, with the middle serratures larger; branches alternate from the middle of the stem, which is a foot and half high, upright, even, and stiffish; corollas white; stamina yellowish white.—Native of Pennsylvania.

2. *Kuhnia Critonia*. Leaves narrow-lanceolate; upper leaves linear, very entire, sessile; the flowers are of a pale yellow: the whole plant is pubescent. It flowers in August and September.—Found on the high mountains of Pennsylvania and Virginia.

Kyllingia; a genus of the class Triandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: ament ovate or oblong, imbricated; scales oblong, distinguishing the flowers. *Glume*: unequal, compressed, bivalve; valves lanceolate, channelled, acute, much shorter than the corolla, the one shorter than the other. *Corolla*: glume longer than the calix, compressed, bivalve; valves keeled, unequal, divaricated at the tips, of which one is larger, lanceolate, very sharp, complicated, embracing the margin of the other; the other shorter, narrower. *Stamina*: filamenta three, awl-shaped, flat; antheræ linear, erect. *Pistil*: germen obovate, flattened, gibbose on one edge; style filiform; stigmas two or three, capillary. *Pericarp*: none; the glumes of the corolla preserving the seed till ripe. *Seed*: oblong, three-sided, destitute of hair. **ESSENTIAL CHARACTER.** *Ament*: ovate, oblong, imbricate. *Flowers*: with a bivalve calix.—The species are,

1. *Kyllingia Monocephala*. Culm filiform, three-sided; head globular, sessile; involucre three-leaved, very long.—Native of the West Indies, where it is very common; also of Japan, and of the Society Isles.

2. *Kyllingia Triceps*. Heads terminating in threes, or thereabouts, glomerate, sessile; culm half a foot high, commonly decumbent at the base, naked, three-cornered.—Native of both Indies, Japan, and the Society Isles.

3. *Kyllingia Panicea*. Umbel terminating with spikes, sessile and peduncled, cylindrical, imbricated; universal involucre four-leaved, or thereabouts; partial none; culm setaceous, three-sided, a span high, without knots, leafy at bottom, naked above.—Native of the East Indies, and Malabar.

4. *Kyllingia Filiformis*. Umbel terminating, simple; spikes sessile and peduncled, ovate; spikelets ovate, acute; involucre three-leaved; partial none.—Native of Jamaica and Hispaniola.

5. *Kyllingia Umbellata*. Umbel terminating; spikes sessile and peduncled, cylindrical, squarrose; universal involucre many-leaved; partial three-leaved; culm three-sided, striated, slender, a foot at the base, naked above.—Found by Koenig in the East Indies.

6. *Kyllingia Sumatrensis*. Umbel terminating; spikes sessile and peduncled, cylindrical, squarrose; universal involucre many-leaved; partial none.—Found by Wennerberg, in Sumatra.

7. *Kyllingia Cypernia*. Culm three-sided, striated, leafy at the base; umbel simple; spikes strict, sessile; universal involucre many-leaved, very long; partial none.—Native of the East Indies.

8. *Kyllingia Pumila*. Culm setaceous; floscules diandrous; capitulum globose, sessile, solitary; involucre short.—It flowers and grows in the western parts of South Carolina and Georgia.

ERRATA.—Page 747, col. 2. Title of second subdivision of Impatiens, for "many-coloured," read "many-flowered."—After 27. *Iris Ramosa*, page 760, should follow *Iris Cuprea*, in page 762; and after 46. *Iris Bituminosa*, page 761, should be placed *Iris Prismatica*.—At page 769, should be introduced, after 10. *Juncus Punctatorius*, the three new species of *Juncus*, from page 770, namely, *Bicornis*,—*Setaceus*,—and *Marginatus*,—substituting the word *Culm* for *Stalk*.—And instead of what follows the word "leaves" at 30. *Juncus Tenuis*, read "canaliculate; corymb terminal, dichotomous, shorter than the bractes; capsules oblong, obtuse, shorter than the calix."

END OF THE FIRST VOLUME.

THE UNIVERSAL HERBAL;

OR,

BOTANICAL, MEDICAL, AND AGRICULTURAL Dictionary.

L A C

LABATIA; (so called from the celebrated Dominican Friar, Father Labat,) a genus of the class Tetrandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth four-leaved, permanent; the two opposite leaflets erect; the two smaller ones ovate, obtuse, concave. *Corolla*: one-petalled, subcampanulated; tube shorter than the calix; border quadrifid; divisions upright, obtuse, small; with two opposite smaller divisions, situated in the partition of the corolla. *Stamina*: filamenta four, length of the corolla, upright, awl-shaped, contiguous to the pistil; antheræ sharp-pointed, upright. *Pistil*: germen roundish, minute, superior; style awl-shaped, length of the stamina; stigma simple, obtuse. *Pericarp*: capsule large, roundish, rough, four-celled. *Seeds*: solitary, oblong, compressed. **ESSENTIAL CHARACTER.** *Calix*: four-leaved, inferior. *Corolla*: subcampanulate, four-cleft, with two minute segments in the divisions of the corolla; capsule four-celled. *Seeds*: solitary.—The species are,

1. *Labatia Sessiliflora*. Flowers sessile.—Native of Hispaniola.
2. *Labatia Guianensis*. Flowers peduncled. This is a tree forty feet high or more, and three feet in diameter, with a russet-coloured wrinkled bark; and a whitish, hard, compact wood.—Native of Guiana, in the forests by the river Sinemari.

Labrador Tea. See *Ledum*.

Laburnum. See *Cytisus*.

Lac, or *Gum Lac*. See *Croton Lacciferum*.

Lace Bark. See *Daphne Lagetto*.

Lachenalia; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: petals six, erected into a tube, oblong, connate at the base, unequal, the three exterior ones shorter, often callous at the tip. *Stamina*: filamenta six, awl-shaped, upright, growing to the base of the petals, and of the length with them; antheræ oblong. *Pistil*: germen superior, subovate; style awl-shaped, length of the stamina; stigma simple. *Pericarp*:

capsule subovate, three-winged, three-celled. *Seeds*: several, globose, affixed to the receptacle. **ESSENTIAL CHARACTER.** *Corolla*: six-parted; the three outer petals difform. *Capsules*: three-winged; cells many-seeded. *Seeds*: globular, affixed to the receptacle.—The plants of this genus must be preserved with other Cape bulbs, in a warm border, covered with glasses, or in a dry-stove, or glass-case. They will mostly bear forcing, and their flowering may be hastened by keeping them warm in the stove; they are increased by offsets from the bulbs, or by seeds, when they produce any.—The species are,

1. *Lachenalia Orchioides*; *Spotted-leaved Lachenalia*. Corollas bell-shaped, the three inner petals longer; flowers sessile; leaves lanceolate, shorter than the scape; bulb round, whitish. The whole plant smooth.—Native of the Cape of Good Hope.

2. *Lachenalia Pallida*; *Pale-flowered Lachenalia*. Corollas bell-shaped, the three inner petals longer; flowers on very short peduncles, horizontal; leaves linear, oblong, longer than the scape; bulb roundish, flattened a little, the size of a hazel-nut; petals whitish.—Native of the Cape of Good Hope.

3. *Lachenalia Contaminata*; *Mix-coloured Lachenalia*. Corollas bell-shaped, the three upper petals longer; flowers peduncled; leaves linear, awl-shaped, channelled.—Native of the Cape of Good Hope.

4. *Lachenalia Tricolor*; *Three-coloured Lachenalia*. Corollas cylindrical, the three inner petals twice the length of the others, emarginate; flowers peduncled, pendulous; the stem is almost comose with the abundance of awl-shaped bractes that spring out below the upper rudiments of flowers; it varies with yellow, saffron-coloured, blood-red, purple, at the tip, and greenish yellow corollas; also, in the proportion between the inner and outer petals, and in the breadth of the leaves.—Native of the Cape of Good Hope.

5. *Lachenalia Pendula*; *Pendulous Lachenalia*. Corollas cylindrical, the three inner petals longer, entire; flowers

peduncled, pendulous; peduncles filiform, red, half an inch long.—Native of the Cape of Good Hope.

6. *Lachenalia Viridis*; *Green-flowered Lachenalia*. Corollas cylindrical, the three outer petals very long, awl-shaped; bulb roundish; the whole plant inodorous and smooth; corollas entirely green.—Native of the Cape of Good Hope.

7. *Lachenalia Orthopetala*. Corollas funnel-form, tubular, the three outer petals a little shorter, bluntish; flowers erect, subpedicelled; bulb round, whitish; flowers upright, on short pale pedicels, inodorous, about thirty, the upper ones abortive; antheræ purple; germen green.—Native of the Cape of Good Hope.

8. *Lachenalia Pustulata*. Corollas cylindrical, the three inner petals one fourth longer than the outer, blunt; flowers erect, subsessile; leaves lanceolate-linear, pustuled; bulb roundish.—Native of the Cape of Good Hope.

9. *Lachenalia Violacea*. Corollas cylindrical, three-sided, the three inner petals reflex, a little longer than the outer; flowers pendulous, peduncled; leaves oblong, spotted on the back; bulb roundish, white, larger than a hazel-nut; the whole of the plant is smooth; flowers small, smelling like Rue.—Native of the Cape of Good Hope.

10. *Lachenalia Patula*. Corollas bell-shaped; inner petals spreading or reflex, longer than the outer; flowers erect, peduncled; leaves linear-lanceolate, shorter than the scape, unspotted; bulb roundish, brown, the size of a pea; the whole plant is smooth; corolla, filamenta, and style white.—Native of the Cape of Good Hope.

11. *Lachenalia Punctata*. Corollas tubular, incurved, inner petals a little longer than the outer, the lowest a little shorter than the two others; flowers nodding, peduncled; leaves lanceolate-linear, dotted; bulb roundish, white; flowers elegant, inodorous; corolla whitish, the outer petals thickly spread, with red dots all over both surfaces.—Native of the Cape of Good Hope.

12. *Lachenalia Hirta*. Corollas bell-shaped, peduncled; leaves linear, rough-haired.—Native the Cape of Good Hope.

Lachnæa; a genus of the class Octandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leafed, permanent; tube long and slender; border four-parted, unequal; the upper segment the smallest, the other three segments reflex, the middle one larger. *Corolla*: none. *Stamina*: filamenta eight, setaceous, upright, nearly the length of the flower; antheræ simple. *Pistil*: germen ovate; style filiform, inserted into the side of the germen, length of the stamina; stigma headed, hispid. *Pericarp*: none; fruit in the bottom of the calix. *Seed*: single, ovate, obliquely acute. *Observe*. This genus differs from *Passerina* only in having an unequal calix. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: four-cleft, with an unequal border. *Seed*: one, like a berry.—The species are,

1. *Lachnæa Erioccephala*; *Woolly-headed Lachnæa*. Heads solitary, woolly; leaves imbricate, in four rows, linear, convex.—Native of the Cape of Good Hope.

2. *Lachnæa Conglomerata*; *Cluster-headed Lachnæa*. Heads clustered; leaves lax, cylindrical, truncate, in four rows.—Native of the Cape of Good Hope.

Lacis; a genus of the class Polyandria, order Digynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: none. *Stamina*: filamenta very many (forty) capillary, winged on both sides below, inserted into the receptacle, which is girt with twelve spines; antheræ oblong, bifid at the base, acute, incumbent. *Pistil*: germen oblong, angular, striated; styles two, incurved; stigmas obtuse. *Pericarp*: capsule ovate, eight-streaked, one-celled, bivalve. *Seeds*: very many, very

small, affixed to a free ovate receptacle. **ESSENTIAL CHARACTER.** *Calix*: none. *Corolla*: none; filamenta winged on both sides below. *Receptacle*: girt with twelve spines; capsule ovate, eight-streaked, one-celled, two-valved, many-seeded.—The only known species is,

1. *Lacis Fluvialis*. Stems branching, decumbent; branches cylindrical, rough to the touch. The Caribbees call this plant *Moureron*.—It is a native of Guiana, and has been found only on the rocks of the great cascade of the river Sinemari; it is attached to the rocks by packets of small fibres, and, except the flowering branches, is entirely under water.

Lacistema; a genus of the class Monandria, order Digynia.—GENERIC CHARACTER. *Calix*: ament common, imbricated on all sides, columnar; scales one-flowered, ovate, concave; two small linear squamules being placed at the sides beneath the corolla, within the scale. *Corolla*: one-petalled, four-parted; tube none; divisions lanceolate, sharp, suberect; nectary one-leafed, rotate, entire, smaller than the corolla, concave. *Stamina*: filamenta single, situated in the middle of the nectary with the germen, upright, incurved above the middle over the germen, bifid at the top; antheræ minute, roundish. *Pistil*: germen globose; styles two, very short, recurved; stigmas simple. *Pericarp*: berry foot-stalked, obovate, oblong, one-celled. *Seed*: single, oblong. **ESSENTIAL CHARACTER.** *Calix*: scale of the ament. *Corolla*: four-parted. *Filamenta*: bifid; berry pedicelled, one-seeded.—The only species yet described is,

1. *Lacistema Myricoides*. Stem arborescent; branches round, somewhat knotty, ash-coloured, naked, smoothish, spreading, branched; branchlets greenish, leafy, smooth; leaves alternate, ovate, acuminate, smooth, somewhat wrinkled with very minute transverse veins; spikes only two or three lines in length.—Observed by Rolander in Surinam, and by Swartz in Jamaica.

Lactuca; a genus of the class Syngenesia, order Polygamia *Æqualis*.—GENERIC CHARACTER. *Calix*: common, imbricated, cylindric; scales very many, sharp, membranaceous on the margin. *Corolla*: compound, imbricated, uniform; corollets hermaphrodite, very many, equal; proper one-petalled, ligulate, truncated, four or five-toothed. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: germen subovate; style filiform, length of the stamina; stigmas two, reflex. *Pericarp*: none; calix converging, ovate, cylindric. *Seeds*: solitary, ovate, acuminate, even, compressed. *Down*: capillary, on a long stipe attenuated below. *Receptacle*: naked. **ESSENTIAL CHARACTER.** *Calix*: imbricate, cylindric, with a membranaceous margin. *Receptacle*: naked. *Seeds*: even, with a simple, stipitate down.—The species are,

1. *Lactuca Quercina*; *Oak-leaved Lettuce*. Leaves runcinate, toothletted, acute, even underneath; stem smooth; root perennial, fleshy. It resembles the wild more than the garden Lettuce. The leaves are of a deeper green, and resemble those of the Oak, whence its name.—Native of Sweden and Germany.

2. *Lactuca Intybacea*; *Endive-leaved Lettuce*. Leaves runcinate, tooth-ciliate, blunt, embracing; stem paniced; the whole plant is smooth and milky; corollets sulphur-coloured.—Native of South America.

3. *Lactuca Sativa*; *Garden Lettuce*. Leaves rounded; stem-leaves cordate; stem corymbd; stem strong, round, two feet or three quarters of a yard in height, bearing abundance of small yellow flowers. This plant has long been celebrated for its cooling and wholesome properties; and, as it contains a quantity of milky juice of an opiate nature, it in

consequence promotes sleep; and it is also in some degree laxative and aperient, and very proper for hot bilious dispositions. The seeds are of an emollient nature; they unite with water by trituration into an emulsion or milky liquor, which has nothing of the aperient bitterness of the milky juice of the leaves; it is very similar to the emulsion of almonds, but more cooling in its nature, and therefore a better medicine in those disorders which arise from acrimony and irritation. —The native country of this plant is not known. The Germans call it *Gartensalat*; the Dutch, *Tuinsalade*, or *Latuw*; the French, *La Laitue cultivée ou commune*. *Lactuca*, a little changed, is the prevailing word in the European languages for Lettuce. The Russians, Danes, and Swedes, call it *Lak-tuk*; the Italians, *Lattuga*; the Spaniards, *Lechuga*; and the Portuguese, *Leituga*. The several varieties cultivated for use in kitchen-gardens, are, 1. Common, or Garden Lettuce; 2. Cabbage Lettuce; 3. Cilicia; 4. Dutch Brown; 5. Aleppo; 6. Imperial; 7. Green Capuchin; 8. Versailles, or Upright White Cos; 9. Black Cos; 10. Red Capuchin; 11. Roman; 12. Prince; 13. Royal; 14. Egyptian Cos. —*Propagation and Culture*. We shall here give directions for the cultivation of this valuable and wholesome article of diet, at some length. The Common Lettuce is sown for cutting very young, to mix with other salad herbs, and is only different from the Cabbage Lettuce in being a degeneracy therefrom; or rather the Cabbage Lettuce is an improvement by frequent cultivation upon the Common Lettuce; for if the seeds be saved from such plants of the former as did not cabbage closely, the plants produced from that seed will degenerate to the first sort, which is by the gardeners called Lapped Lettuce, to distinguish it from the other, which they call Cabbage Lettuce. The seeds of the Common Lettuce, which are usually saved from any of the plants without regard to their goodness, are generally sold at a very cheap rate, especially in dry seasons, when they always seed in the greatest abundance, and is sometimes sold for Cabbage Lettuce, so that the buyer is disappointed in his crop. This sort therefore should never be cultivated to be cut up very young, although it be the only kind fit for that purpose. It may be sown at any time of the year, observing only to sow it in shady borders during hot weather, and, in the spring and autumn, upon warm borders; but in winter it should be sown under glasses, otherwise it is subject to be destroyed by severe frosts. The Cabbage Lettuce may also be sown at different times of the year, in order to have a continuation of it through the whole season. The first crop is generally sown in February, upon a warm spot of ground; and when the plants are come up, they should be thinned out to the distance of ten inches each way, which may be done by hoeing them out, as is practised for turnips, carrots, onions, &c. provided you have no occasion for the superfluous plants; otherwise they may be drawn up, and transplanted into another spot of ground at the same distance, which, if done before the plants are too large, they will succeed very well, though they will not be so large as those which are left upon the spot where they are sown, but they will come somewhat later, which will be of service where people do not continue sowing every fortnight or three weeks in summer. You must also observe, in sowing the succeeding crops, as the season advances, to choose a shady moist situation, but not under the drip of trees, which would cause them to run up into seed in summer before they cabbage. In the beginning of August, sow the seeds for the last crop, which is to stand over winter, thinly upon a good light soil, in a warm situation; and when the plants are come up, they must be hoed out, that they may stand singly. Remove all the weeds, and in

the beginning of October transplant them into warm borders, where, if the winter is not severe, they will stand very well; but in order to be sure of a crop, it will be advisable to plant a few upon a bed pretty close together, where they may be arched over with hoops, and in severe frosts covered with mats, straw, or pease-haulm, to secure them from being destroyed. In the spring of the year they may be transplanted out into a rich soil, ten inches asunder; but still those that grew under the wall, if they escaped the winter, and were suffered to remain, will cabbage sooner than those which are removed again; but you must observe not to place them too close to the wall, which would occasion their growing up tall, and prevent their being large or hard. In order to save good seeds of this kind, look over your Lettuces while in perfection, and mark such as are very hard and grow low, by placing sticks in the ground close to them. Pull up all that you do not want for seed, as soon as they begin to run up, lest, when they come to flower, the farina of the bad should mix with the good, and so degenerate the seeds, which should always be saved either from those which stood through the winter, or those which were sown early in the spring, for the later ones very seldom perfect their seeds. The Cilicia, Imperial, Royal, Black, White, and Upright Cos Lettuces, may be sown first at the latter end of February, or the beginning of March, upon a moderate hot-bed, or on a warm light soil, in a sheltered situation; and when the plants are come up, and are fit to transplant, those which are sown on the hot-bed should be transplanted on another warm bed about four inches asunder row from row, and two inches' distance in the rows, shading them from the sun until they have taken new root; after which, they should have a larger share of air daily, to prevent their drawing up weak; but in favourable seasons, transplant them at the beginning of April, where they are to remain, placing them sixteen inches apart each way, because the large sorts must not be placed near each other: those sown in the full ground will be later before they come up, and should be either hoed out, or transplanted into another spot of ground, especially if the soil be good. After they have taken fresh root, weed them carefully, which is all the culture they will require, except the Black Cos Lettuce, which should be tied up when they are full grown, in the manner as directed for blanching of Endive, (See *Cichorium Endivia*), to whiten their inner leaves, and render them crisp, otherwise they are seldom good for much, rarely cabbaging without this assistance. When they are in perfection, mark those you intend for seed, as already directed for the Common Cabbage Lettuce, and take away the rest, for the reasons above given. These sorts may be continued throughout the lettuce season, by sowing them in April, May, and June, observing to sow the late crops in a shady situation, otherwise they will run up to seed before they grow to any size; but in the middle of September you may sow of these sorts to abide the winter. These should be transplanted either under glasses or into a bed, which should be arched over with hoops, in order to be covered in the winter, without which covering the plants would often be destroyed. At the same time, too closely covering them brings on mouldiness and rot; and, as they require abundance of fresh air, they should only be covered in heavy rains and frosty weather. In the spring, these plants should be planted out into a rich light soil, allowing them at least sixteen inches' distance each way; for if they are planted too close, they are very subject to grow tall, but seldom cabbage well. From this crop, if they succeed well, it will be proper to save your seeds; though you should also save from that crop sown on the hot-bed in the spring, because some-

times it happens, that the first may fail by a wet season, when the plants are full in flower, and the second crop may succeed, by having a more favourable season afterwards; and no harm can arise should both the crops succeed. The most valuable of all the sorts of Lettuce in England, are the Egyptian Green Cos, and the Versailles or White Cos, and the Cilicia, though some people are very fond of the Royal and Imperial Lettuces, which seldom sell so well, or are so much esteemed, as the other: the White Cos obtained the preference, until the Egyptian Green Cos was introduced, which is so much sweeter and tenderer than the White Cos, that all good judges pronounce it the best sort of Lettuce yet known; it will endure the cold of our ordinary winters as well as the White Cos; but at the season of its cabbaging, if there happen to be much wet, it is very subject to rot. The Brown, Dutch, and Green Capuchin Lettuces, are very hardy, and may be sown at the same seasons as was directed for the Common Cabbage Lettuce, and are very proper to plant under a wall or hedge to stand the winter, where many times these will abide when most of the other sorts are destroyed, and therefore they will prove very acceptable at a time when few other sorts are to be had: they will also endure more heat and drought than most other sorts of Lettuce, which renders them very proper for late sowing; for it often happens, in very hot weather, that the other sorts of Lettuce will run up to seed in a few days after they are cabbaged, whereas these will abide nearly a fortnight in good order, especially if care be taken to cut the forwardest first, leaving those that are not so hard cabbaged to the last. If some plants of these two last sorts are planted under frames, on a moderate hot-bed in October, they will be fit for use in April, which will prove acceptable to those who are lovers of Lettuce; and, being covered by glasses, will render them tender. In saving these seeds, the same care should be taken to preserve only such as are very large and well cabbaged, otherwise the seeds will degenerate, and be good for little. The Red Capuchin, Roman, and Prince's Lettuces, are pretty varieties, and cabbage very early, for which reason a few of them may be preserved, as may also some of the Aleppo, for the beauty of its spotted leaves; though very few people care for any of these sorts at table, when the other more valuable ones are to be obtained: but the former do very well in a scarcity of the latter, and are very proper for soups. The seeds of these must also be saved from such as cabbage best, otherwise they will degenerate, and be good for little. In saving seeds of all these sorts of Lettuce, never suffer two sorts to stand near each other, for, by their farina mixing, they will both vary from their original, and partake of each other; and there should be a stake fixed down by the side of each, to which the stem should be fastened, to prevent their being broken, or blown out of the ground by wind, to which the Cilicia, Cos, and the other large-growing Lettuces, are very subject when they are in flower. Observe also to cut such branches of the large-growing Lettuce as ripen first, and not wait to have the seed of the whole plant ripe together, which never happens; but, on the contrary, some branches will be ripe a fortnight or three weeks before others; and when you cut them, they must be spread upon a coarse cloth in a dry place, that the seeds may dry, after which you should beat them out, and dry them again, and then preserve them for use, taking care to hang them up where mice and other vermin cannot come at them, for if they do they will soon eat them up. The wild sorts are easily raised from seed: Perennial Lettuce spreads at the root; it is increased by suckers.

4. *Lactuca Scariola*; *Prickly Lettuce*. Leaves vertical, prickly on the keel; root biennial, and, like the rest of the plant, very full of milky juice; stem erect, two or three feet high, round, prickly, leafy, branched at the top into a sort of panicle, consisting of numerous small pale yellow flowers; seeds ovate, of a ferruginous blackish colour.—Native of the southern parts of Europe; found with us near Denney Abbey, and on the borders of fields in the Isle of Ely. See the preceding species.

5. *Lactuca Virosa*; *Strong-scented Lettuce*. Leaves horizontal, prickly on the keel, and toothed; root biennial; stem from two to four feet high, prickly below; flowers numerous, yellow, sessile, or on short peduncles, with a small leaf at the base of each, and others still smaller on them.—Native of the south of Europe, in hedges, on ditch-banks, and borders of fields. In England, at the World's End near Stepney, and on the banks of the Thames between Blackwall and Woolwich; found also at Burwell Pit, in Cambridgeshire; on old walls near Bungay in Suffolk; in Marston Lane, Oxfordshire; and in a stone quarry at Thorp Arch, in Yorkshire. The *Lactuca Scariola* of Hudson is a variety of this species. This plant abounds with a milky juice, the opiate power of which is of very considerable strength, inasmuch that it may occasionally be used in the manner of common opium. It may be collected by suffering the juice to drain from the wounded parts of the plant; and then, by drying in the manner of opium, it may be made into pills. Sir John Hill, in his *British Herbal*, recommends this to be practised in April and May. When dried, it dissolves freely in wine, and forms an excellent anodyne; the dose of which, a tea-spoonful in a glass of water, answers all the purposes of laudanum. Dr. Collins relates twenty-four cases of dropsy, out of which twenty-three were cured by taking the extract, in doses from eighteen grains to three drachms in twenty-four hours; it commonly proves laxative, promotes urine and gentle sweats, and removes thirst: it must be prepared when the plant is in flower. A syrup, made from a strong infusion of the plant, is an excellent anodyne medicine; it eases the most violent pains of the colic and other disorders, and gently disposes the patient to sleep, producing all the good effects of a gentle opiate, without possessing any of the bad qualities of that narcotic drug. If this plant cannot be easily procured, the Common Garden Lettuce may be substituted for it; but it is not so effectual. See the third species.

6. *Lactuca Saligna*; *Least Lettuce*. Leaves hastate, linear, sessile, prickly on the keel; flowers nearly sessile, small, yellow.—Native of France, Saxony, the Palatinate, Silesia, Switzerland, Austria, Carniola, Piedmont, and England, on the banks of ditches, and in pastures on a chalky soil. See the third species.

7. *Lactuca Tuberosa*; *Tuberous-rooted Lettuce*. Leaves spinulose-toothed; stem almost simple; root tuberous, manifold; the whole plant even; the calix abounds with a white milk, which turns to an orange-colour when exposed to the air; corollas pale blue, purple; flowers few. See the third species.

8. *Lactuca Canadensis*; *Canadian Lettuce*. Leaves lanceolate, ensiform, embracing, toothed, unarmed.—Native of Canada. See the third species.

9. *Lactuca Indica*; *Indian Lettuce*. Leaves lanceolate, ensiform, sessile, unequally toothed.—Native of the East Indies; observed in Java. See the third species.

10. *Lactuca Perennis*; *Perennial Lettuce*. Leaves linear, tooth-pinnate; segments toothed upwards; root perennial, composed of many long fleshy fibres, which abound with a

milky juice, and spread pretty far in the ground; flowers terminating on slender branching peduncles, sustaining from two to four flowers; corollas deep blue, or purple.—Native of Germany, Italy, and France. See the third species.

11. *Lactuca Angustana*. Leaves entire, toothed, sharply hooked; the midrib smooth; root annual, fusiform; stem the height of a man; flowers on short peduncles, and panicled; florets commonly twelve; seed dirty white; the whole plant is very smooth and milky, without any virose smell.—It is found in sandy places, by the torrent that descends from the Great St. Bernard, and in the valley of Aost, between St. Pierre and Villanova. See the third species.

12. *Lactuca Elongata*. Leaves smooth underneath; lower leaves runcinate, very entire, embracing the stem; radical leaves dentated, those on the top of the plant lanceolate; flowers corymbose, paniculate. It grows from three to six feet high, and the flowers are small and of a pale yellow colour.—Found in sandy places on road sides, in fertile soils, from Carolina to Canada.

13. *Lactuca Graminifolia*. Stalk erect, simple; panicles aphyllous, lax; branches rariflorous; all the flowers pedunculated.—Found by Michaux in Lower Carolina.

Ladies' Bedstraw. See *Galium*.

Ladies' Bower. See *Clematis*.

Ladies' Finger. See *Anthyllis*.

Ladies' Hair. See *Briza*.

Ladies' Mantle. See *Alchemilla*.

Ladies' Slipper. See *Cypripedium*.

Ladies' Smock. See *Cardamine*.

Ladies' Traces. See *Ophrys*.

Laetia; a genus of the class Polyandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets oblong, concave, reflex, coloured, withering. *Corolla*: none, or else five petals. *Stamina*: filamenta numerous, capillary, rather shorter than the calix; antheræ roundish. *Pistil*: germen oblong, ending in a filiform style, longer than the stamina; stigma headed, depressed. *Pericarp*: berry globose, three-sided, furrowed with three lines, one-celled, increased internally by a cartilaginous membrane. *Seeds*: very many, nestling, cornered, coated with a pulpy aril. *Observe*. The first species has a fleshy berry, and the second is pentapetalous, with a three-valved capsule. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-petalled, or none; fruit one-celled, three-cornered. *Seeds*: with a pulpy aril.—The species are,

1. *Laetia Apetala*. Flowers apetalous; calices five-leaved, reflex; leaves oval, serrulate, smooth on both sides. This is an upright tree, about twenty feet in height, putting out spreading branches from the very ground. Common peduncles three-flowered, axillary, sustaining white flowers like those of Hawthorn in appearance, size, and smell; they appear in April and May, and fruit in June.—Native of Carthagea, in New Spain.

2. *Laetia Completa*. Flowers petaloid, complete. This is a small branching tree, about nine feet high. Common peduncles axillary, tomentose; fruit reddish-yellow, often obscurely triangular.—Native of Carthagea, flowering in June, and fruiting in August and September.

3. *Laetia Guidonia*. Flowers apetalous; peduncles one-flowered, terminating; leaves oblong, acuminate, serrate, pubescent. This tree grows to a considerable size, is esteemed a fine timber wood, and much used in all sorts of buildings. The filamenta of the flower are very numerous, and in the fruit the lines between the valves are of a beautiful red colour, as well as the placentæ.—Native of Jamaica, where it is called Rodwood.

4. *Laetia Thamnia*. Flowers apetalous; peduncles many-flowered, subdivided, axillary; leaves oblong, acute, subcrenate, shining.—This shrub is found in the red hills above the Angels in Jamaica, but is not common.

Lagerstroemia; a genus of the class Icosandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, six-cleft, bell-shaped, rather acute, smooth, permanent. *Corolla*: petals six, ovate, obtuse, cusped, undulated, contorted; claws filiform, longer than the calix, inserted into the receptacle. *Stamina*: filamenta very many, filiform, longer than the calix, inserted into the calix below the germen, the six exterior ones are twice the thickness of the rest, and are longer than the petals; antheræ oval, incumbent. *Pistil*: germen subglobose; style filiform, length of the longer stamina; stigma simple. *Pericarp*: capsule subglobose, crowned with the style on its bluntish top, six-furrowed, six-celled, six-valved; the *dissepiments* coalescing with the sutures. *Seed*: several, ovate, awl-shaped at the base, compressed, adhering to a central hexagonal pillar. *Observe*. The number of parts sometimes varies. ESSENTIAL CHARACTER. *Calix*: six-cleft, bell-shaped. *Petals*: six, curled. *Stamina*: very many, the six outer thicker than the rest, and longer than the petals.—The species are,

1. *Lagerstroemia Indica*. Leaves alternate, ovate; calices naked, even. The trunk of this tree is about a fathom high, and smooth all over. Corolla purple.—Native of the East Indies, China, Cochinchina, and Japan.

2. *Lagerstroemia Speciosa*. Leaves alternate, ovate; calices and leaves tomentose underneath.—Native of China.

3. *Lagerstroemia Regina*. Leaves opposite, oblong, smooth; calices grooved; trunk erect; branches horizontal, spreading; flowers much larger and more beautiful than those of the first species, colour in the morning that of a pale rose, growing deeper through the day, and acquiring a purple tinge; calix inferior, on the outside beautifully grooved into trapezoid figures.—Native of the East Indies, on many woody mountains of the northern parts of the Circars, where it grows to a tree of a midling size, flowering in the hot season, and ripening seeds in August. It is very beautiful when in flower, and well deserves a conspicuous place in our stoves. We know not of any use that this tree is put to by the natives.

4. *Lagerstroemia Parviflora*. Leaves opposite, oblong, smooth above, downy underneath; calices grooved; trunk erect, with smooth ash-coloured bark; branches numerous; flowers small, white.—This small tree is a native of the Circar mountains; it flowers during the hot season, and the seeds are ripe in August and September. The wood is used by the natives for various æconomical purposes, but neither the beauty of the flower, nor the appearance of the tree, recommend it for ornament on a footing with the other species.

Lagæcia; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: involucre universal eight-leaved; leaflets feather-toothed, ciliated, reflex, containing the umbellule; involucre proper four-leaved; leaflets hair-feathered, involving a single foot-stalk, shorter than the leaflet itself; perianth proper five-leaved; hair many-cleft, superior. *Corolla*: petals five, two-horned, shorter than the calix. *Stamina*: filamenta five, capillary, length of the corolla; antheræ roundish. *Pistil*: germen roundish, below the receptacle of the perianth; style length of the stamina; stigmas two, the one truncated. *Pericarp*: none. *Seeds*: solitary, ovate-oblong, crowned by the perianth. *Observe*. The alternate seed is abortive. ESSENTIAL CHARACTER. Involucre universal and partial,

Petals: bifid. *Seeds*: solitary, inferior.—The only known species is,

1. *Lagoecia Cuminoides*; *Wild or Bastard Cumin*. This is an annual plant, about a foot high, with leaves resembling those of Honey-wort. The flowers, which appear in June and July, are collected into spherical heads at the extremity of the stalks, and are of a greenish-yellow colour.—Native of the Levant. Sow the seeds in autumn on a warm border soon after they are ripe; or if they be permitted to scatter, they will soon come up of themselves. When the seeds are sown in the spring, they commonly remain in the ground a year, and sometimes two or three years before they grow.

Lagunæa; a genus of the class Monadelphia, order Polyandria.—GENERIC CHARACTER. *Calix*: perianth one-leaved, bell-shaped, somewhat cornered, half five-cleft, permanent; according to Cavanilles, deciduous. *Corolla*: petals five, ovate-oblong, obtuse, spreading, affixed to the base of the tube of the stamina. *Stamina*: filamenta several, (from twenty-five to thirty,) conjoined into a tube below, in the top and sides of the tube receding from it and free; antheræ roundish. *Pistil*: germen ovate-oblong; style thread-shaped, longer than the stamina, five-cleft at the tip; divisions spreading, or undivided; stigmas headed. *Pericarp*: capsule ovate, oblong, somewhat five-cornered, five-celled, five-valved; partitions contrary. *Seeds*: some, roundish, three-sided.

Observe. The genus *Hibiscus* shews that both had better be conjoined than separated. ESSENTIAL CHARACTER. *Calix*: simple, five-cusped; style simple; stigma peltated; capsule five-celled, five-valved.—Plants of this genus may be propagated and cultivated in the same manner with those species of *Hibiscus* which come from hot countries. See *Hibiscus*.—The species are,

1. *Lagunæa Aculeata*; *Prickly Lagunæa*. Stem prickly, tomentose; leaves deeply many-parted; flowers axillary, solitary; flowers on short peduncles; corolla yellow, twice as long as the calix, spreading.—Native of Coromandel, near Pondicherry, where it is called *Cattacacheree* by the natives.

2. *Lagunæa Solandra*; *Maple-leaved Lagunæa*. Leaves subcordate, three-cusped, serrate; flowers corymbed. This plant is about two feet high, and hirsute; stem upright, round, stiff, the thickness of a goose-quill; flowers corymb racemed at the ends of the stem and branches; corolla purplish white, truly one-petalled, with a short cylindrical tube.—Found in the Isle of Bourbon. See *Hibiscus Solandra*, which is the same plant. It ripens seed in England, and may be increased by them.

3. *Lagunæa Ternata*; *Three-leaved Lagunæa*. Stem herbaceous, villose; lower leaves ternate, with the middle leaflet very long; upper leaves subhastate; flowers axillary, solitary; root round, not very fibrous.—Native of Senegal.

Lagurus; a genus of the class Triandria, order Digynia.—GENERIC CHARACTER. *Calix*: glume one-flowered, bivalve; valves long, linear, spreading, very thin, each ending in a villose awn. *Corolla*: bivalve, thicker than the calix; valve exterior, longer, terminated by two small upright awns; a third awn from the middle of the back of the same valve, reflex-twisted; valve interior, small, sharp; nectary two-leaved; leaflets lanceolate, obtuse, gibbous at the base. *Stamina*: filamenta three, capillary; antheræ oblong. *Pistil*: germen top-shaped; styles two, setaceous, villose; stigmas simple. *Pericarp*: none. *Corolla*: grows to the seed. *Seed*: solitary, oblong, covered, awned. ESSENTIAL CHARACTER. *Calix*: two-valved, with a villose awn. *Corolla*: having on the outer petal two terminating awns, and a third dorsal, one twisted back.—The only known species is,

1. *Lagurus Ovatus*. This is an annual grass, growing to the height of a foot or eighteen inches, and even more, very soft and hoary, as are also the leaves and spikes.—Native of the south of Europe, France, Italy, Sicily, and Portugal.

Lamb's Lettuce. See *Valeriana*.

Lamium; a genus of the class Didynamia, order Gymnospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, wider above, five-toothed, awned, nearly equal, permanent. *Corolla*: one-petalled, ringent; tube cylindric, very short; border gaping; throat inflated, compressed, gibbous, marked on each edge with a reflex toothlet; upper lip arched, roundish, obtuse, entire; lower lip shorter, obcordate, emarginate, reflex. *Stamina*: filamenta four, awl-shaped, covered beneath the upper lip, two of them longer; antheræ oblong, hairy. *Pistil*: germen four-cleft; style filiform, length and situation of the stamina; stigma two-cleft, sharp. *Pericarp*: none. *Calix*: open, and bearing in its bosom the seeds, which are flat at top. *Seeds*: four, short, three-sided, convex on one side, truncated on both sides. ESSENTIAL CHARACTER. *Corolla*: upper lip entire, vaulted; lower two-lobed; throat with a reflex toothlet on each side.—The species are,

1. *Lamium Orvala*; *Baum-leaved Archangel*. Leaves cordate, unequally and sharply serrate; corollas inflated at the throat; calix coloured; root perennial; stem from half a yard to nearly a yard high; corolla an inch long, of a deep red colour. Indeed the brilliance and size of the flowers have secured it admittance into the garden, while all the rest are excluded, notwithstanding its strong and unpleasant smell. The Orvala Garganica of Linneus is a mere variety of this, owing its apparent difference to having grown in a moist shady place.—Native of Italy, Silesia, and Hungary. It rarely produces good seeds in England, nor do the roots propagate very fast. October is the best time to part and remove these roots, but they must not be transplanted oftener than every third year, if they are required to flower strongly. It is hardy, and thrives best in a soft loamy soil. Mr. Curtis says it grows readily; but that flowering about the end of April, it is then apt to be injured if cold winds prevail, unless it be placed in a sheltered part of the garden.

2. *Lamium Levigatum*; *Smooth Archangel*. Leaves cordate, wrinkled; stem even; calices smooth, the length of the tube of the corolla; root perennial, somewhat creeping; whorls of flowers separated by leaves, ten in a whorl at most.—Native of Italy, Silesia, and Siberia. See the sixth species.

3. *Lamium Rugosum*; *Wrinkled Archangel*. Leaves cordate, acute, wrinkled, hairy with the stem; whorls many-flowered; a single bristle-shaped tooth at the throat. This plant is about a foot high. The flowers are like those of the common sort, and of a deep rose-colour. Sometimes in cold situations it produces curled leaves, round like those of the Lime-tree.—Native of Italy. See the sixth species.

4. *Lamium Garganicum*; *Woolly Archangel*. Leaves cordate, pubescent; throat of the corolla inflated; tube straight, a double tooth on each side; root perennial, creeping; stems many, thick, a foot high; flowers in whorls from the upper joints, large, of a pale purplish colour, continuing in succession most part of the summer.—Native of Italy, Silesia, China, Cochin-china, and Japan. It is propagated by seeds, and its roots spread very fast.

5. *Lamium Maculatum*; *Spotted Archangel*. Leaves cordate, acuminate; whorls ten-flowered. This is very nearly allied to the next sort. It differs from it in having a purple corolla; the leaves marked with a longitudinal white area, which however disappears in summer; the petioles not widened; flowers five on each side, not ten; two teeth on

each side of the throat, the upper one bristle-shaped.—Native of Germany, Silesia, Dauphiny, and Italy. See the next species.

6. *Lamium Album*; *White Archangel*, or *Dead Nettle*. Leaves cordate, acuminate, serrate, petioled; whorls twenty-flowered; root perennial, white, jointed, creeping; stems numerous, a foot high, unbranched, slender at bottom, hollow, slightly hairy, sometimes almost smooth; in exposed situations reddish purple; the young shoots erect and ascending. It is common in hedges, on banks, by road-sides, and in corn-fields, flowering in April and May, when it is much resorted to by bees, for the honey secreted into the bottom of the tube by the gland that surrounds the base of the germen. Hence it is called in some countries *Bee-nettle*, which is corrupted into *Bean-nettle*. It has also the name of *Die-nettle*, which is a corruption of *Dead-nettle*, and that, as well as *Blind-nettle*, means a nettle without stings. The Germans call it, *Taube Nessel*; the Dutch, *Doovenetel*, *Hondsnetel*; the Danes, *Doednelde*, *Doevnelde*, *Blindnelde*; the Swedes, *Blindnesla*, *Pipnesla*; the French, *Lamier*, *Lamion*, *Ortie blanche* or *morte*, *Archangelique*; the Italians, *Ortiga morta*, or *Bianca*; the Spaniards, *Ortiga muerta* or *blanca*, *Lamio blanco*, *Arcangelica*; and the Portuguese, *Ortiga morta*, or *branca*, *Lamia branca*.—This plant has a disagreeable smell when bruised. The *Phalæna Chrysis*, or burnished brass moth, feeds on it. Linneus says the leaves are eaten in Sweden as a pot-herb in the spring. No cattle however appear to touch it; and having a strong creeping perennial root, it should be extirpated, unless retained for medical purposes. The flowers made into a conserve are an excellent remedy for that troublesome, weakening, and oftentimes obstinate and dangerous, female complaint, the fluor albus or whites. Doses of a few grains, gradually increased, have been found very effectual. The whole plant is of an astringent nature, and the dried roots are sometimes given with success in fluxes. A strong infusion of the leaves bids fair to answer the same purposes, and may be serviceable in all other kinds of weakness and debility. It propagates itself copiously by the roots; so also do the second, third, fifth, seventh, ninth, tenth, and thirteenth species, which are probably mere varieties.

7. *Lamium Bifidum*. Leaves cordate, acuminate; upper lip of the corolla bifid; segments divaricated; stems a foot or eighteen inches high, procumbent, tinged with red at bottom, and branched there; flowers white, appearing in February and March.—It is an annual plant, native of Italy, near Naples, several places on the coast of Tuscany, and of the isle of Elba. See the preceding species.

8. *Lamium Purpureum*; *Purple Archangel*. Leaves cordate, blunt, petioled; root annual, fibrous; stems several, at the bottom weak and branched, near the top almost naked, and frequently coloured, six inches or more in height, hollow, and somewhat rugged; flowers growing thickly together on the tops of the stalks in whorls, six together, in a double row; corolla red; seeds pale brown, triangular, truncate, margined.—This, like the sixth species, is common in most parts of Europe, in the same situations, and is a common weed in gardens and other cultivated land; flowering a great part of the year, from April to September, and in mild seasons both earlier and later. Bees resort also to this for the honey-juice in the flowers. Linneus says it is boiled in Upland, a province of Sweden, as a pot-herb. The herb and flowers, either fresh or dried, afford a decoction that is good for floodings, bleedings at the nose, spitting of blood, or any kind of hæmorrhage. The leaves are also useful to staunch wounds, when bruised, and outwardly applied. It is propagated by seeds.

9. *Lamium Dissectum*; *Cut-leaved Archangel*. Leaves deeply and irregularly cut; stem-leaves decurrent. It is annual, and not unfrequent, according to Ray, in kitchen-gardens and fallow fields. Mr. Curtis observed it on a bank between Pimlico and Chelsea; and Mr. Robson, about Darlington. See the sixth species.

10. *Lamium Molle*; *Pellitory-leaved Archangel*. Leaves petioled, slightly toothed, lower cordate, upper ovate; flowers white.—Native place unknown.

11. *Lamium Amplexicaule*; *Perfoliate Archangel*. Floral leaves sessile, embracing, blunt; root annual, fibrous, whitish; stems several, nine inches or a foot high, nearly upright, smooth, with a few opposite branches; flowers in whorls, to fifteen, perfect and imperfect; the latter short, a little longer than the calix, the tips very red, hairy, and closed; the former four times the length of the calix, bright purple, generally breaking out from the top of the stem. The imperfect corollas are very hairy, of a bright red colour, and the mouth closed. The tube of the perfect ones is very long, cylindrical, and nearly upright; the edge of the throat is turned back, spotted, and has two little teeth; the neck is a little prominent; the upper lip hirsute, and nearly entire; the lower turning down, and dividing into two lobes, which are spotted with purple. The imperfect flowers appear in February and March, the perfect ones not till May or June: if the progress of the flowers be watched, it will be found that the corolla is gradually enlarged in different flowers, till the weather being sufficiently warm, they come forth fully formed. The imperfect flowers are neither rudiments of the long ones, nor are they barren, for they have both stamina and pistillum. Linneus informs us that this plant scarcely ever produces perfect flowers in Sweden. Here then we have a process somewhat similar to what is observed in the Violet, and some other plants, in which perfect seed is produced, although the corolla be not perfectly formed; analogous to what happens in the animal kingdom: when a caterpillar, previously to its changing into the *Chrysalis* state, has been deprived of its proper quantity of food, the fly comes forth perfect in all its parts except the wings, which are crumpled up, and never expand.—This plant is common in most parts of Europe, in cultivated ground, on light soils, and on walls. The old name of it is *Great Henbit*. It is propagated by the seeds, and by the roots.

12. *Lamium Multifidum*. Leaves many-parted.—Native of the Levant.

13. *Lamium Moschatum*; *Musky Archangel*. Leaves cordate, blunt, smooth; floral-leaves sessile; calices deeply gashed; stems eight or nine inches high; flowers white, appearing in April; the leaves are marked with white, somewhat like those of the autumnal Cyclamen; they are smooth, and in dry weather have a musky scent, but in wet weather are fetid. The seeds ripen in June. It is probably a mere variety of the sixth species.

14. *Lamium Hispidulum*. Stalk hispid; leaves widely cordate, pubescent; axils one-flowered; flowers large, white.—Found in the shady woods of Tennessee, North America.

Lanaria; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: one-petalled, subcampanulated, outwardly wool-haired; tube short; border six-parted; divisions linear-lanceolate, somewhat spreading. *Stamina*: filamenta six, filiform, shorter than the corolla, inserted into the base of the divisions; antheræ ovate, somewhat incumbent. *Pistil*: germen inferior, top-shaped, outwardly woolly; style filiform, upright, length of the stamina; stigmas three-cleft. *Pericarp*: capsule ovate, three-celled. *Seeds*: few. ESSENTIAL CHA-

CHARACTER. *Corolla*: superior, woolly, larger than the filaments; border six-parted, somewhat spreading. *Capsule*: three-celled.—The only known species is,

1. *Lanaria Plumosa*; *Woolly Lanaria*. Root fibrous; stem woolly, upright; stem-leaves sessile, nerved, smooth; flowers terminating, in a close panicle; spathes simple. It has the habit of *Wachendorfia*.—Native of the Cape of Good Hope.

Land.—It is correctly stated, in an able work on the landed property of England, that land, viewed in the light of agriculture, is the foundation on which it rests, the materials on which it operates, and the visible source of its productions. This may generally be considered as being composed of three distinct parts; the soil, the subsoil, and the base, or substructure on which they rest. The soil, or plant-feeding stratum, is equally various in quality and depth. The soils of cultivated lands, however, have their limits as to depth. These limits may, it is conceived, be fixed at three and fifteen inches. For although in many instances the component parts of land are pretty uniform to a greater depth than fifteen inches, a uniformity of colour and vegetative quality seldom reaches to that depth. The influence of the atmosphere, the fibres of vegetables living and decayed, the operations of animalculæ and larger animals that inhabit soils, and above all the powerful effects of manures, tend to furnish the surface-mould with qualities which the substrata have not the means of acquiring. The medium depth of cultivated soils in England may, we suppose, be set down at about nine inches. For although a majority of the cultivated soils of the kingdom may not reach that depth, it is probable that the major part might be advantageously sunk to that depth by proper management. The subsoil, or intervening stratum of land, is still less definite with regard to depth. In some instances, as where the cultivated soil rests upon rocks, it may be said to be wanting, though in most cases of this a stratum of a gravelly nature, composed of broken rock and earth, is found between them. In many cases a regular bed of gravel, sand, or other earth, intervenes between the soil and the substructure; while in others a uniform mass of earthy materials reaches to a great depth. If therefore a definite thickness or depth may be assigned to the subsoil, it must be in a degree arbitrary, or without any degree of accuracy or correctness. It seems evident that the soil affords nourishment and stability to agricultural plants; and that the subsoil assigns them temperature, with respect to moisture and internal warmth. If the subsoil be of such a nature, or so situated, as to receive and retain more moisture than is requisite for the natural growth of plants, their health is injured. If it not only holds water in its own pores, but freely communicates it to those of the soil, the more valuable plants in agriculture will give way to ranker herbage, let the surface soil be what it may. On the contrary, if an open stratum of sufficient depth intervenes between the cultivated soil and the base, to permit the superfluous moisture which filters through the soil to pass off, the plants in cultivation will be relieved from collected moisture in the immediate region of their feeding fibres, though the substructure may be charged to the full with water. Hence, where nature has not furnished land with this valuable interstratum, it is the business of art to remedy the defect, which is generally best done by draining off the superfluous moisture to a sufficient depth to prevent its evil effects on the soil, and thereby supplying the required stratum. In doing this, the artist must be led by the given properties of the base, and he can seldom lower it to any determinate or arbitrary depth. Nevertheless he should endeavour to form an adequate idea of the medium

depth required, in doing which much depends on the specific quality of the soil. Sand will hold up water that is lodged at its base to a much greater height than gravel, a stratum of which one foot deep forms a drier subsoil than a bed of sand of twice or three times that thickness. But clean sand or gravel is rarely found in land, sand and gravelly loams being the most common in absorbent subsoils; and these are capable of raising and holding up water to a considerable height. Let us therefore admit that effective subsoils may vary from one to two feet, and fix the medium depth at eighteen inches; by thus placing the mean depth of soils at nine inches, and that of subsoils at eighteen inches, we shall place the base or substructure of the land at twenty-seven inches beneath its surface, which is a depth of land equally conformable with theory and with practice. To this depth drains may be sunk at a moderate expense; especially covered stone drains, which would be effectual, and yet not be liable to injury in tillage. In the practice of skilful workmen, the depth of ordinary subsoil drains varies from eighteen inches to three feet, according to the circumstances of the given case, and the method of draining employed. After this general view of the component parts of land, and of their due arrangement, the common varieties of it, as they are given by soil, subsoil, and base, remain to be considered. We shall divide them into classes, and mark the varieties of each.—*First Class.* This comprehends such lands as are liable to surface-water only, with their absorbent strata (if any) open, so as freely to discharge the superfluous water that falls upon them. The varieties of this are, first, where the soil, the subsoil, and the base, are repellent, or in a state of moistness impenetrable by water; as clay and strong deep clayey loam. The second, where the soil is repellent, the subsoil absorbent, and the base repellent. The third, where the soil is repellent, the subsoil and base absorbent, or in a state of moistness conducting water; as sand, gravel, open rock, and the lighter more open loams. The fourth, where the soil, the subsoil, and the base, are absorbent. The fifth, where the soil and the subsoil are absorbent, but the base repellent. And the sixth, where the soil is absorbent, the subsoil repellent, and the base absorbent or repellent.—*Second Class.* This includes such lands as are liable to surface-water only, with their absorbent strata closed, or permitting an imperfect discharge, either for want of sufficient descent, or by reason of impervious strata, or beds of impenetrable materials. The varieties of which are, first, where the soil is repellent, the subsoil absorbent, and the base repellent or absorbent. The second, where the soil and the subsoil are absorbent, but the base repellent or absorbent. The third, where the absorbent and repellent strata or masses are thrown together irregularly, or not disposed in regular strata, which correspond with the surface or upper part.—*Third Class.* This comprises such lands as are liable not only to surface-waters, but to those which are subterranean, and which either descend from higher grounds in their respective neighbourhoods, or rise beneath them from subjacent reservoirs; the absorbent strata of this class being closed, and thereby rendered retentive, as in the second class or kind of land. The varieties of which are, first, where the soil is absorbent or repellent; the substrata absorbent and closed, and uniformly charged with descending waters by an even stratum of gravel, free-sand, or some other similar material. The second, where the same soil and substrata are partially charged with descending waters, through veins of sand, or gravel, or fissures of rock, &c. The third, where the soil is repellent or absorbent, the subsoil absorbent and closed, and uniformly charged with descending waters; the base repellent, with a

Corolla: bell-shaped, expanding; petals six, ovate, flat, conjoined at the base; with the tips thickish and stiffish. *Stamina*: filamenta six, setaceous, very short; antheræ oblong, obtuse, quadrangular, upright, distant. *Pistil*: germen roundish, inferior; style clavate, obtuse; stigma setaceous, upright, sharp, longer than the stamina. *Pericarp*: capsule top-shaped, three-celled, three-valved. *Seeds*: several, roundish. *Observe*. The third species has a filiform style. **ESSENTIAL CHARACTER.** *Corolla*: bell-shaped, six-parted, thickened at the tips; stigma simple.—These bulbs are increased by offsets, which the two first sorts put out pretty plentifully in a favourable situation, where they are not too often removed. They should have a soft loamy soil, and an exposure to the east. Plant the roots six inches asunder, and four or five inches deep. They should not be transplanted oftener than every third year. A north or east border is best for them; and the proper soil a mixture of loam and bog-earth. In different aspects, however, their flowering may be forwarded or protracted, and thus a longer succession of these and other flowers produced.—The species are,

1. *Leucoium Vernal*; *Great Spring Snowdrop*. Spathe one-flowered; style club-shaped; leaves flat; bulb oblong, shaped like that of Daffodil, but smaller; scape angular, near a foot high, hollow, and channelled; corolla much larger than that of the Common Snowdrop; and the ends of the petals are green. The flowers, which at first sight resemble those of the Common Snowdrop, are easily distinguished by the absence of the three-leaved nectary. They do not come out so soon by a month. This plant being of a different genus from the true Snowdrop, ought certainly to have another English name; Mr Curtis therefore calls it *Spring Snowflake*. Parkinson had already called it *Great Early Bulbous Violet*; and Gerarde, *Late-flowering Bulbous Violet*.—Native of Italy, the south of France, Germany, Austria, and Switzerland.

2. *Leucoium Æstivum*; *Summer Snowdrop*. Spathe many-flowered; styles club-shaped; leaves flat; bulb the size of a chesnut, somewhat ovate, outwardly pale brown, inwardly white; coats numerous, thin, and closely compacted; flowers pendulous, growing all one way, having little scent; petals white, finely grooved within, not at all uniting at bottom, the tips thickish, a little puckered, and marked with a green spot; seeds large, black, and glossy. The flowers appear at the end of April or the beginning of May, and there is a succession of them during three weeks, or longer in cool weather. Mr. Curtis, to distinguish it from *Galanthus*, names it *Summer Snowflake*: in the gardens it is known by the name of *Great Summer Snowdrop*; *Late or Tall Snowdrop*: Parkinson calls it *Great Late-flowering Bulbous Violet*; and Gerarde, *Great Many-flowering Bulbous Violet*.—Native of Hungary, Austria, Carniola, Tuscany, and Silesia. Mr. Curtis first observed it in England between Greenwich and Woolwich, about half a mile below the former place, close by the Thames side, just about high water mark, along with Reed, Marsh Marigold, and other common water-plants, and in a similar situation to that in which it is found wild in Austria. It has also been found wild in the Isle of Dogs, which is the opposite shore, and grows more luxuriantly in those places than in gardens, where it seldom has a soil or situation sufficiently moist. Mr. Gough found it on a small island about three miles south of Kendal, upon the dam of a gunpowder mill.

3. *Leucoium Autumnale*; *Autumnal Snowdrop*. Spathe two-leaved, many-flowered; styles and leaves filiform; bulb thick for the size of the plant, composed of many glutinous coats, bitter, covered with a whitish membrane. It is dis-

tinguished by its four or five capillary leaves, which begin to spring up after the flower is past, when the seeds are ripening, and sometimes after the heads are ripe. They abide all the winter and spring following, and wither away in the beginning of summer, leaving the scape to appear naked. The flowers are a little reddish at the bottom next the stalk.—It flowers in September, and is a native of Portugal and Spain.

4. *Leucoium Strumosum*. Spathe two-leaved, many-flowered; flowers erect; style inflated at the base, globular; bulb roundish, white, less than a hazel-nut; scape flexuose, erect, slender, about half a foot high, roundish, terminated by a spreading umbel of from three to seven flowers; flowers without scent, coming out successively; petals white within, purplish without. It flowers in November, and is a native of the Cape of Good Hope, and must be housed and treated in the same way as other Cape bulbs.

Levisanus; a genus of the class Pentandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth common hemispheric, imbricated, many-flowered; leaflets linear; perianth proper, one-leafed, superior, five-toothed, sharp, upright, permanent. *Corolla*: petals five; claws slender; borders oblong, shorter. *Stamina*: filamenta five, capillary, inserted into the bottom of the perianth; antheræ oblong. *Pistil*: germen top-shaped, inferior; styles two, conjoined into one, or else distinct and approximated, capillary; stigma simple. *Pericarp*: berry corticated, ovate, incrustated by the calix, with the tip free, two-celled. *Seeds*: five or six, oblong, compressed. *Receptacle of the seeds*: fungous, large in the middle of the partition. *Receptacle*: common, globose, villose, chaffy. *Observe*. The fruit of all the species is not yet known. **ESSENTIAL CHARACTER.** Flowers aggregate, *Calix*: one-leafed, superior, five-cleft. *Corolla*: five-petalled, superior. *Filamenta*: superior; filamenta inserted into the base of the perianth; styles two, conjoined; berry two-celled. *Seeds*: five or six, compressed.—The species are,

1. *Levisanus Nodiflorus*. Leaves imbricate, three-sided, acute; calix five-parted; petals five, linear, having a chink on each side of the claw, with a converging margin; receptacle double.—Native of the Cape of Good Hope.

2. *Levisanus Paleaceus*. Leaves in five rows, imbricate, pressed close; corymb terminating; chaffs of the heads standing out; flowers many, panicked; styles two; receptacle hairy.—Native of the Cape of Good Hope.

3. *Levisanus Abrotanoides*. Leaves linear-lanceolate, spreading, three-sided, callous at the tip; heads of flowers globular, terminating, subumbelled, on round peduncles; corolla white.—Native of the Cape of Good Hope.

4. *Levisanus Radiatus*. Leaves linear, three-sided; calix rayed; the inner leaflets coloured; stem from a foot to two feet in height, the size of a swan's quill, upright, round, leafy, scarred, determinately branched, dichotomous or trichotomous; the branches rod-like, hairy; common corolla dusky, not at all glutinous.—Native of the Cape of Good Hope.

5. *Levisanus Glutinosus*. Leaves linear, three-sided; calix rayed, all the leaflets coloured; stem from a foot to two feet in height, the size of a swan's quill, upright, round, grooved, scarred, very much branched; branches proliferous, hairy; common corolla dusky, very glutinous; receptacle chaffy.—Native of the Cape of Good Hope.

Lewisia; a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: coloured, scariose, from seven to nine-leaved, patent. *Corolla*: containing from fourteen to eighteen petals, white, lanceolate, patent. *Stamina*: filamenta from fourteen to eighteen, inserted on the receptacle, opposite to the petals, filiform, shorter than the

calix; antheræ oblong, erect. *Pistil*: style filiform, a little longer than the stamina, three-cleft above; stigmata three, bifid; germen above ovate, glabrous. *Pericarp*: capsules oblong, trilobular; locules bispermous. *Seeds*: lenticular, shining black. **ESSENTIAL CHARACTER.** *Calix*: seven to nine-leaved, scarious. *Petals*: from fourteen to eighteen. *Style*: trifid. *Capsule*: trilobular, polyspermous; seed shining.—There is only one species known.

1. *Lewisia Rediviva*. Root fusiform, branchy, and of a bloody hue; radical leaves linear, subcarinate, somewhat obtuse; pedicel geniculated at the base. The calix is elegantly red-veined, of a consistency like paper.—It flowers in July, and was found by Lewis on the banks of Clark's river.

Leysera; a genus of the class Syngenesia, order Polygamia Superflua.—**GENERIC CHARACTER.** *Calix*: common ovate, imbricate: scales obtuse, concave, harsh. *Corolla*: compound, rayed; corollets hermaphrodite, tubular, several in the disk; females strap-shaped, several in the ray; proper of the hermaphrodite funnel-form, five-toothed, rather upright; female strap-shaped, lanceolate, entire. *Stamina*: in the hermaphrodites, filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: in the hermaphrodites, germen small; style filiform; stigma bifid. *Pericarp*: none; calix unchanged. *Seed*: in the hermaphrodites solitary, oblong; down five-bristled, feathery, long, within which is a very short chaffy crown; in the females very similar; down with the chaffy crown alone, without feathers. *Receptacle*: naked; chaffs of the rays alone, separating the flowers. **ESSENTIAL CHARACTER.** *Calix*: scarious; down chaffy; in the disk feathery also. *Receptacle*: subpaleaceous.—The species are,

1. *Leysera Gnaphalodes*; *Woolly Leysera*. Leaves scattered; flowers peduncled. This is an evergreen shrub, with a balsamic smell; the trunk and older branches are leafless and brown; the younger ones very closely covered with leaves, and spreading out very wide; peduncles filiform at the ends of the branchlets, solitary, one-flowered; corolla yellow; seeds brownish. It flowers from July to September.—Native of the Cape of Good Hope.

2. *Leysera Callicornia*. Leaves in three rows; flowers subsessile; receptacle flat, with raised dots in the middle, naked, rugged, and having a single row of chaffs in circumference.—Native of the Cape of Good Hope.

3. *Leysera Paleacea*. Leaves three-sided, callous at the tip, and curved back. The whole receptacle covered with chaffs almost the length of the flowers; the whole crown of the seed membranaceous, and none downy. Hence it agrees in character with *Bupththalmum*; but it resembles the preceding so much, as scarcely to be distinguished from it in appearance.—Native of the Cape of Good Hope.

Liatris; a genus of the class Syngenesia, order Polygamia Equalis.—**GENERIC CHARACTER.** *Calix*: common oblong, imbricated, with several subovate unarmed coloured scales. *Corolla*: compound, tubular, uniform; corollets hermaphrodite, equal; proper one-petalled, funnel-form; tube inflex; border five-cleft; divisions recurved. *Stamina*: filamenta five, capillary, very short; antheræ cylindric, tubular. *Pistil*: germen oblong; style filiform, very long, bifid to the stamina, straight; stigmas rather sharp. *Pericarp*: none; calix unchanged. *Seeds*: solitary, cornered; down feathery, coloured, sessile. *Receptacle*: naked, flat. **ESSENTIAL CHARACTER.** *Calix*: oblong, imbricate, awnless, coloured. *Down*: feathered, coloured. *Receptacle*: naked, hollow, dotted.—The species are,

1. *Liatris Noveboracensis*; *Long-leaved Liatris*. Leaves lanceolate-oblong, serrate, pendulous; stems several, ten or twelve feet high, smooth, deeply striated, pale green, stout,

rigid, straight, not branching except at top; flowers in a sort of umbel, or corymb at top; the florets are of a deep purple colour; and the calix is tinged with purple.—Native not only of New York, but of Virginia, Carolina, and other parts of North America.

2. *Liatris Præalta*; *Tall Liatris*. Leaves lanceolate-oblong, serrate, spreading, hirsute underneath; root perennial, large, striking deep into the ground; stems branching only at top, seven or eight feet high, purplish, straight, deeply striated; flowers in loose erect bunches at the ends of the branches; florets pale purple; receptacle naked. It flowers from September to November.—Native of Virginia, Carolina, and other parts of North America.

3. *Liatris Glauca*; *Glaucous Liatris*. Leaves ovate-oblong, acuminate, serrate; flowers corymbd; calices roundish; root perennial; stems six or seven feet high, purple and channelled; florets dark purple, inclining to violet.—Native of Maryland, Virginia, and Carolina.

4. *Liatris Squarrosa*; *Rough headed Liatris*. Leaves linear; calices squarrose, subsessile, acuminate, lateral; root tuberous; stems simple, from two to three feet in height; peduncles an inch long, alternate from the upper axils; heads of flowers squarrose, with leafy scales standing out and bent back. It flowers in July and August.—Native of Carolina, and most of the provinces of North America.

5. *Liatris Scariosa*; *Rugged-cupped Liatris*. Leaves lanceolate, quite entire; calices squarrose, peduncled, blunt; root large, tuberous; stem one, strong, channelled, three or four feet high; flowers purple, in a long loose spike, at the upper part of the stem, on pretty long blunt peduncles; they have large rough calices, composed of wedge-shaped scales; the flowers at the top of the spike open first. It flowers in August, but the seeds do not ripen here.—Native of Virginia.

6. *Liatris Pilosa*; *Hairy-leaved Liatris*. Leaves linear, hairy; flowers axillary, on long peduncles; stem hairy, from three to five feet in height; flowers purple, sessile, subimbricate, in spikes; calices many-flowered, with the scales pressed close; stems simple. It flowers in September and October.—Native of North America.

7. *Liatris Speciosa*; *Hairy-cupped Liatris*. Leaves linear-sickled; flowers sessile, in spikes; calicine leaflets rough-haired, acute; inner elongated, coloured at the tip; stem upright, two feet high, tomentose; calices five-flowered, red at the tip. It flowers in October.—Native of Carolina and Georgia.

8. *Liatris Spicata*; *Spiked Liatris*. Leaves linear, ciliate at the base; flowers in spikes, sessile, lateral; stem simple; root tuberous; stem smooth, three feet high; flowers purple, subimbricate, on short peduncles. It flowers from August to October.—Native of North America, where it is called *Throatwort*, the root being discutient.

9. *Liatris Heterophylla*. Stalk simple, glabrous; leaves lanceolate, glabrous, smooth; upper leaves linear-lanceolate, very much smaller than the lower ones; calix spicate, slightly pedunculate, subsquarrose; squames lanceolate, acute, naked.—It grows in South Carolina and Georgia.

10. *Liatris Cylindracea*. Leaves grassy; squames rounded at the top, abruptly mucronated; calix subsessile, cylindrical, with few flowers, which appear from August to October, and is a native of South Carolina and the Illinois.

11. *Liatris Gracilis*. Stalk simple, glabrous; leaves linear, naked; calix racemose, subglobose; pedicels elongate, patent, squamose-bracteolate; squames oblong. It flowers from August to October.—Native of Georgia.

12. *Liatris Sphæroidea*. Stalk simple, pubescent; leaves smooth; upper leaves lanceolate-linear; lower ones petiolate, lato-lanceolate; calices racemose, solitary, alternate, subglo-

bosc; squames ovate, erect, ciliate at the margin. The flowers are large and handsome.—Native of the high mountains of Virginia and Carolina.

13. *Liatris Pauciflora*. Stalk simple, glabrous; leaves linear; panicles virgated, leafy; branches with few flowers; calices subsessile; squames lanceolate, erect, acute, glabrous.—It grows in Georgia.

14. *Liatris Tomentosa*. Stalk very simple; leaves cuneate-lanceolate, rough; corymb with few flowers, depressed, divaricated; calix tomentose; squames ovate, acute. It grows to the height of about eighteen inches, and is found in the open swamps of Virginia and Carolina.

Lichen; a genus of the class Cryptogamia, order Algæ.—**GENERIC CHARACTER.** *Male*. Flowers: *Vesicles* conglomerated, extremely small, crowded or scattered on the disk, margin, or tips of the fronds. *Female*. Flowers on the same or on a distinct plant. *Receptacle*: roundish, flat-tish, convex. *Tubercle*: concave. *Scutella*: subrevolute, affixed to the margin. *Pelta*: often differing from the frond in colour, within containing the seeds disposed in rows. *Observe*. The powder adhering to some Lichens seems rather to be of the nature of buds than of male fructifications.—The extremely numerous species of this genus may be conveniently divided into the following sections, some of which by some authors are made distinct genera.

Lepra: a dusty crust. Fructifications, hardly any.

Tubercularia: a leafless crust: the fructifications tubercles.

Scutellaria: a leafless crust. Frs. Scutellæ or shields.

Collema. Fronds foliaceous, gelatinous. Frs. Scutellæ or shields.

Imbricata: fronds subfoliaceous, membranaceous, imbricated, depressed, flexile. Frs. Scutellæ.

Physcia. Fronds foliaceous, membranaceous, depressed, or ascendant, tubular within. Frs. Scutellæ sessile or pedunculated.

Lobaria. Fronds foliaceous, membranaceous, ascending, flexile. Frs. Scutellæ sessile or pedunculated.

Cornicularia. Fronds foliaceous, membranaceous, or cartilaginous, somewhat upright, narrowed, stiff, with somewhat sharp extremities; scutellæ sometimes terminal, transverse.

Stricta. Fronds foliaceous, subcoriaceous, scattered over beneath with white excavated points. Frs. Scutellæ or peltæ.

Peltigeræ. Fronds foliaceous, coriaceous, ascending, soft. Frs. Peltæ.

Umbilicaria. Fronds foliaceous, upright, stiff, shielded. Frs. Scutellæ.

Pyxidium. Stems upright, funnel-form, hollow within; tubercles fungiform, unequal, marginal.

Cladonia. Stems upright, somewhat columnar, branchy, hollow within, with the appearance of a shrub; the axillæ often perforated. Frs. Fungiform tubercles.

Stereocaulon. Stems erect, rather columnar, simple or branchy, solid. Frs. Tubercles.

Usnea. Stems erect or pendulous, filamentous, simple or branched. Frs. Scutellæ.

Of this very numerous genus Dr. Withering, in the third edition of his *Arrangements*, has enumerated no fewer than two hundred and sixteen species, besides a great number of varieties. Many of these are of considerable use for dyeing, and other æconomical purposes: the most remarkable are the following. Doubtless if more accurate and extensive trials were made on these neglected plants, many other æconomical uses for them might be detected; or at least many more of the same species might be applied to the same purposes.

Lichen Aphthosus. The country people make an infusion of it in milk, and give it to children who have the thrush.

In large doses it operates by purging and vomiting, and destroys worms.

Lichen Calcareus. So called because it is peculiar to limestone rocks: when dried, powdered, and steeped in urine, is used to dye scarlet, by the Welsh and the inhabitants of the Orkneys. The colour is said to be very fine.

Lichen Caninus; called also *Lichen Cinereus Terrestris*, or *Ash-coloured Ground Liverwort*. This species is one of the articles in the celebrated Dr. Mead's prescription for the cure of Hydrophobia, concerning which he says, "I can safely affirm that I have never known this method to fail of success where it has been followed before the hydrophobia began: although in the course of about thirty years, besides the experience made by others both in town and country, I have used it a thousand times. I have often wished that I knew so certain a remedy in any other disease." The method is as follows. Let the patient be bled at the arm, nine or ten ounces. Take of the herb called in Latin, *Lichen Cinereus Terrestris*, or in English, *Ash-coloured Ground Liverwort*, cleaned, dried, and powdered, half an ounce. Of black pepper powdered two drachms. Mix these well together, and divide the whole into four doses, one of which must be taken every morning fasting, for four successive mornings, in half a pint of cow's milk warm. After these four doses are taken, the patient must go into the cold bath, or a cold spring, or river, every morning, fasting, for a month: he must be dipped all over, but not stay in (with his head above water) longer than half a minute, if the water be very cold. After this he must go in three times a week for a fortnight longer.—Later writers have declared that this remedy has been tried without success; but as Dr. Mead was no quack, but the most eminent physician of his time, and as no certain cure for hydrophobia has yet been found, we think it would be some consolation to those who may be under the melancholy necessity of endeavouring to prevent or cure that dreadful calamity, and even to the poor sufferers themselves, to have done every thing in their power, by employing the best means known to avert the awful catastrophe. It is of course understood that Dr. Mead's prescription is intended for those only who have been bitten by a rabid animal, and have either neglected to cut out the wounded part through ignorance; or from a doubt whether the animal were really mad; and also where the removal of the affected part would endanger the patient's life: for it cannot be too universally made known, that for the bad effects of the bite of mad dogs or venomous reptiles, excision of the bitten part is the only certain preventive, and should be instantly performed wherever death is not likely to be the consequence. Hesitating to do this, has cost thousands their lives. An instance of the fortitude and presence of mind necessary on these occasions, we shall subjoin. In Bengal, some years ago, when Capt. Hutchinson, on returning home in the night, attended by a servant with a torch, casually trod on a cobra de capella, which instantly bit him on the calf of his leg: the poison of this snake being more immediately mortal than the bite of any other, Capt. H. with great presence of mind cut out with his knife a large portion of the calf of his leg, and applied the burning torch to cauterize the wound, which prevented the poison from having its usual effect.

Lichen Islandicus. The Icelanders boil this in broth, or dry and convert it into bread. They likewise make gruel with it to mix with milk; but the first decoction is always thrown away, for it is apt to purge. It has recently obtained a reputation for curing consumptive complaints; but upon what foundation that reputation rest, we cannot determine.

Lichen Omphalodes, dyes wool of a brown reddish colour, or a dull but durable crimson, paler, but more lasting than

that of Orchall. It is prepared by the country people in Ireland, by steeping it in stale urine, adding a little salt to it, and afterwards making it up into balls with lime. Wool dyed with it, and then dipped in the blue vat, becomes of a beautiful purple. With rotten oak it makes a good dark brown frieze. Wool dyed with red wood or sanders, and afterwards in this, which is called Cork, Corker, or Arcell, becomes of a dark reddish. It has also been used as a styptic.

Lichen Parellus. Litmus is prepared from this species. For this purpose it is gathered from the rocks in the north of England, and sent to London in casks.

Lichen Plicatus, called *Hairy Tree*, is a very singular plant of the mosses; it grows to the branches of old oaks and other trees, and hangs down from them in tufts composed of long strings, which are frequently a foot or more in length, and the whole of them together two or three inches thick: each cluster consists of a great number of stems and branches, the largest of which do not exceed a small packthread in thickness; they are of a greyish colour, and consist of soft bark, and a firm white fibre within; the bark often appears crooked, and the branches exhibit an appearance of being jointed. The whole plant, as it grows, appears sapless, and is destitute of leaves, or any other appearance of vegetation. It is found in some of our largest forests, but is seldom to be met with any where else. The powder of this moss is an excellent astringent: it should be dried in an oven, and, after being beaten in a mortar, passed through a sieve; the white fibres will remain after the other parts have gone through the sieve, and are of no manner of use, the other parts possessing all the virtues. It is good against the whites, immoderate menstrual discharges, bloody fluxes, and spitting of blood; and deserves to be much more regarded than it is at present. The dose is half a drachm, or two scruples.

Lichen Prunastri, has a remarkable property of imbibing and retaining odours, and is therefore the basis of many perfumed powders.

Lichen Pulmonarius. This dyes woollen cloth of a durable orange. In Herefordshire they dye stockings with it of a durable brown: and it has obtained a name for curing the consumption, but probably without reason.

Lichen Pustulatus. Linneus says, that a beautiful red colour may be prepared from this. It may be converted into an exceedingly black paint.

Lichen Pyxidatus. This little plant is common on ditch-banks, by the sides of woods or heaths, and in most other dry barren places; it consists of a thin leafy substance, which spreads on the surface of the ground, and a kind of little cup, resembling wine-glasses rising from it. The leafy part is dry, and without juice, divided into several segments or portions, which are irregularly notched, grey or greenish on the upper side, and whitish underneath. The cups are in general about half an inch high, and are each of them supported on thick clumsy stems; they are open at the mouth, of a gray colour, with a mixture of green and other colours, sprinkled over with a fine mealy substance on the surface; sometimes they grow one from the edge of another, three or four stages high, and we frequently see many other accidental varieties; they likewise bear at certain seasons little brown lumps, which are supposed, and not without a degree of probability, to be the seeds of the plant. The whole of this moss, when used, is to be taken fresh from the ground, shaken clean, and boiled in water, till the decoction is very strong; there is then to be added an equal quantity of milk to the liquor, which is then to be sweetened with honey; and will afterwards form an excellent medicine for coughs in children, particularly for the chin-cough or hooping-cough.

Lichen Rangiferinus. This is well known to be the chief food of the Rein Deer, which will grow fat upon it; and that animal supplies the contented Laplander with every article of life, as is set forth by Linneus in his *Flora Laponica*.

Lichen Roccella, or *Orchall*, is of very great importance as an article of commerce, being extremely valuable for dyeing wool or silk any shade of purple or crimson. For this purpose it is steeped in volatile alkali, commonly distilled from urine. In times of scarcity it has been sold at a thousand pounds sterling per ton. It comes chiefly from the Levant, but has been lately discovered to grow in the British dominions.

Lichen Tartareus. This is common on rocks in the north of England and Scotland. It may be known by its peculiarly pungent alkaline smell when moistened. Peasants who can collect twenty or thirty pounds a day, gather it for the dyers, and sell it for a penny a pound. They choose such specimens as are of a firm dense texture, and never scrape the same rock oftener than once in five years. It is prepared for use with volatile alkali and alum, but the exact process is kept a secret by the manufacturers at Glasgow. When sold to the dyers, it appears in the form of a purple powder, called *Cudbear*, a corruption of Cuthbert, the name of the inventor. This powder, being boiled with woollen yarn, communicates a purple colour to it, but not to vegetable substances; and the colour is far from being permanent.

Licuala; a genus of the class Hexandria, order Monogynia. —GENERIC CHARACTER. *Calix*: perianth three-parted, outwardly hairy, permanent. *Corolla*: three-parted, almost to the base; divisions ovate, acute, concave, deciduous; nectary sertiform, truncated, as short again as the corolla. *Stamina*: filamenta six, inserted into the nectary, upright, very short; antheræ oblong, twin. *Pistil*: germen superior, convex, three-parted, sulcated, smooth; style simple; stigmas two. *Pericarp*: drupe globose, the size of a pea, one-celled. *Seed*: a hard nut. ESSENTIAL CHARACTER. *Flowers*: all hermaphrodite. *Calix* and *Corolla*: three-parted. *Nectary*: sertiform; drupe.—The only known species is,

1. *Licuala Spinosa*. Trunk an ell in height, scarcely so thick as the human arm, jointed, dividing at top into about six branches, each six ells long, hardly a finger in thickness, triangular, grooved above, flat beneath, the lower half sharply serrate at the angles, and the teeth or spinules closely joined. Each of these has a leaf at top spreading like a fan, and divided into rays, all separated to the base. When the plant is mature, the flower-stalk emerges from the middle of the rays, as long as the branches or leaf-stalks, involved in sheaths at the bottom, dividing into five smaller flower-stalks at top, about a hand in length, bearing green heads in three rows expanding into flowers. Rumphius says, that the nut is oblong, very hard, and striated longitudinally.—It is a native of Macassar and Celebes; where they make much use of the narrow leaves for tobacco pipes, and of the middle broad one for wrapping up fruit, &c. The wood is of little use, not being durable.

Lightfootia; a genus of the class Polygamia, order Diœcia. —GENERIC CHARACTER. *Hermaphrodite*. *Calix*: perianth four-leaved; leaflets ovate, concave, expanding. *Corolla*: none. *Stamina*: filamenta numerous, filiform, seated on the receptacle, permanent; antheræ roundish. *Pistil*: germen roundish, style none; stigma sessile, somewhat headed, furrowed. *Pericarp*: berry ovate, umbilicated, one-celled. *Seeds*: from three to six, oblong, compressed, cornered, glossy. *Males* on different individuals. *Calix*: perianth four-leaved; leaflets oblong, concave, equal, coloured. *Ca-*

rolla: none. *Stamina*: filamenta numerous, (twenty-four,) filiform, longer than the calix, inserted into the receptacle; antheræ roundish. *Pistil*: none. *Females* on different individuals; calix as in the male, but larger. *Corolla*: none. *Pistil*: germen oblong; style none; stigma elevated, quadrangular-headed, furrowed, with convoluted margins, permanent. *Pericarp*: berry oblong, seated on a very small receptacle, umbilicated, one-celled. *Seeds*: three, five, to six, as above. *Observe*. This genus is allied to *Prockia*, with which they agree in calix, stamina, and habit, but differ in the stigma. **ESSENTIAL CHARACTER.** *Calix*: four-leaved. *Corolla*: none. *Female* and *Hermaphrodite*. *Stigma*: sessile; berry umbilicated, one-celled, with from three to six seeds.—The species are,

1. *Lightfootia Serrata*. Leaves oblong-ovate, serrate, acuminate; peduncles lateral, aggregate, one-flowered.—Native of Montserrat.

2. *Lightfootia Thæformis*. Leaves lanceolate-elliptic, serrate, bluntish; peduncles axillary, subsolitary, one-flowered; branches and all the other parts smooth. It has the habit of the Tea-shrub.—Native of the Isle of Bourbon.

3. *Lightfootia Integrifolia*. Leaves subcoriaceous, oblong and obovate, emarginate, almost quite entire; peduncles lateral, subaggregate, one-flowered. This is also a shrub, with round smooth branches, covered with an ash-coloured bark. Flowers larger than in the other sorts.—Native place unknown.

Lignum Campechianum. See *Hæmatoxylum*.

Lignum Colubrinum. See *Strychnos*.

Lignum Corneum. See *Garcinia*.

Lignum Læve. See *Glabraria*.

Lignum Moluccense. See *Croton*.

Lignum Vitæ. See *Guaicum*.

Ligusticum: a genus of the class Pentandria, order Digynia.—**GENERIC CHARACTER.** *Calix*: umbel universal manifold; partial manifold; involucre universal membranaceous, seven-leaved, unequal; partial scarcely four-leaved, membranaceous; perianth proper, five-toothed, obscure. *Corolla*: universal uniform; florets all fertile; proper of five petals, which are equal, involute, flat, entire, inwardly keeled. *Stamina*: filamenta five, capillary, shorter than the corolla; antheræ simple. *Pistil*: germen inferior; styles two, approximated; stigmas simple. *Pericarp*: none; fruit oblong, cornered, five-furrowed, bipartite on each side. *Seeds*: two, oblong, smooth, marked on one side with five elevated striæ, flat on the other side. *Observe*. Male flowers have also been remarked. **ESSENTIAL CHARACTER.** *Fruit*: oblong, five-grooved on both sides. *Corolla*: equal, with involute entire petals.—The seeds of the plants of this genus should be sown in autumn, soon after they are ripe, for when they are kept out of the ground till spring, they seldom grow the first year. When the plants are fit to remove, transplant them into a moist rich border at three feet distance. They all love a moist soil and shady situation.—The species are,

1. *Ligusticum Levisticum*; *Common Lovage*. Leaves manifold; leaflets gashed at top; root strong, fleshy, perennial, striking deep into the ground; stems six or seven feet high, large, and channelled, divided into several branches, each terminated by a large umbel of yellow flowers.—The odour of this plant is very strong, and peculiarly ungrateful; its taste is warm and aromatic. It abounds with a yellowish gummy resinous juice, very much resembling Opoponax. Its qualities are supposed to be similar to those of Angelica and Masterwort, in expelling flatulencies, exciting perspiration, and opening obstructions; it is therefore chiefly used in uterine obstructions. A tea-cup full of the juice with Rhenish

wine, or a decoction of the seeds with wine or mugwort-water, was said by Forestus to be a secret remedy of extraordinary efficacy in slow or laborious parturition. The leaves, eaten as salad, are accounted an emmenagogue. The root and seeds are of a cordial sudorific nature, and many authors of credit recommend the use of them in pestilential disorders. An infusion of the root increases the urinary discharge, removes obstructions of the viscera, brings away gravel, and helps the jaundice: the seeds produce the like effects, and are potent dispersers of wind in the stomach. The roots of Common Lovage will abide many years, and where the seeds are permitted to scatter, the plants will come up without care. This plant flowers in June and July, and the seeds ripen in autumn.—Native of the Alps of Italy, the south of France, and Silesia. It is planted in our gardens for its medicinal qualities.

2. *Ligusticum Scoticum*; *Scotch Lovage*. Leaves bipinnate; stalk about a foot high, and sustains a small umbel of yellow flowers, shaped like the preceding: most authors say the root is perennial. It is much valued in the Isle of Sky. The root is reckoned a good carminative; and an infusion of the leaves in whey, a good purge for calves. It is also used for food, either as salad or boiled like greens.—Native of North America, Sweden, Denmark, and Scotland, where it is found upon the rocks near the coast.

3. *Ligusticum Peloponnense*; *Hemlock-leaved Lovage*. Leaves manifold-pinnate; leaflets pinnately gashed; root thick, fleshy, like that of the Parsnep, striking deep into the ground. When bruised, the leaves emit a fetid odour. Stems three or four feet high, large, and hollow, sustaining large umbels of yellowish flowers.—Native of Switzerland, Austria, Dauphiny, Silesia, Italy, Peloponnesus, and Siberia.

4. *Ligusticum Austriacum*; *Austrian Lovage*. Leaves bipinnate; leaflets confluent, gashed, quite entire; root half a foot long or more, the thickness of the human thumb, often branched, yellowish brown on the outside, pale within, and spongy; stem upright, from two to three feet high, grooved, hollow, without any partitions at the joints; flowers strong-smelling, large, all fertile; petals white. The whole plant is smooth. It flowers from June to August.—Native of Austria, Silesia, and Italy.

5. *Ligusticum Cornubiense*; *Cornish Lovage*. Root-leaves decomposed, gashed; stem-leaves ternate, lanceolate, entire; root perennial, spindle-shaped; stem from two to three feet in height, erect, branched, many-flowered, round, striated, roughish, purple at the base, annual; flowers white, equal, all hermaphrodite. The root contains a yellow resinous juice. This plant, as its name imports, is peculiar to Cornwall, where it grows in thickets, among bushes, and in hedges. It eluded the researches of modern botanists, till Mr. Pennington found it in 1788 in great plenty near Bodmin, where it was also gathered in the following year, though five years afterwards not a single plant could be discovered in that field; but Dr. Withering found it in another place, farther from Bodmin, among furze. Cattle are so fond of it that they eat it down wherever they can get at it.

6. *Ligusticum Peregrinum*; *Parsley-leaved Lovage*. Involucre of the primary umbel scarcely any, of the lateral ones membranaceous at the base; rays somewhat branched; root biennial; stem two feet high, rigid, angular, even; petals yellowish, inflex-emarginate. It resembles Parsley even in smell and taste, but all the parts are thicker and more rigid. It flowers in June and July.—Native of Portugal.

7. *Ligusticum Balearicum*. Leaves pinnate; lowest leaflets augmented with a leaflet; root biennial; stem round, somewhat striated, small in comparison with the umbel, a foot

high; flowers in an umbellet, eight or ten, yellow, all fertile.—Native of Majorca and Minorca, and about Rome.

8. *Ligusticum Candicans*; *Pale Lovage*. Superdecom-pound; leaflets wedge-form, gashed, smooth; universal involucre two-leaved, subfoliaceous; ribs of the seeds membranaceous, smooth. It flowers in July and August.—Native place unknown.

9. *Ligusticum Actæifolium*. Leaflets oval, equally dentated; involucels setaceous; fruits oblong-oval.—It grows to the height of more than three feet, and is found on the river St. Lawrence, and in Virginia near Staunton.

Ligustrum; a genus of the class Diandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, tubular, very small; mouth four-toothed, erect, obtuse. *Corolla*: one-petalled, funnel-form; tube cylindric, longer than the calix; border four-parted, spreading; divisions ovate. *Stamina*: filamenta two, opposite, simple; antheræ upright, almost the length of the corolla. *Pistil*: germen roundish; style very short; stigma two-cleft, obtuse, thickish. *Pericarp*: berry globose, smooth, one-celled. *Seeds*: four, convex on one side, cornered on the other. *Observe*. According to Gärtner, the berry is two-celled; the cells coated with a thin membrane. The seeds are two in each cell. **ESSENTIAL CHARACTER.** *Corolla*: four-cleft. *Berry*: four-seeded.—The species are,

1. *Ligustrum Vulgare*; *Common Privet*. Leaves ovate, obtuse; panicle simple, trichotomous. This shrub is usually about six feet high, branched, the branches opposite, the young ones flexible and purplish. The flowers are sweet-scented; corolla white, but soon changing to a reddish brown. This plant varies in many respects. The leaves sometimes grow by threes, and sometimes are enlarged at the base; they frequently continue green great part of the winter like the Italian Privet, which is also a variety, and rises with a stronger stem, less pliable and more erect branches, and bark of a lighter colour. The regular number of stamina is two, but sometimes there are three or four in a flower, and they have been found with white berries. Thunberg says, that in Japan the leaves are somewhat broader and more blunt than in the European shrub. In point of utility and ornament, few shrubs are preferable to the Common Privet. Its chief use is to form such hedges as are required in dividing gardens for shelter or ornament; and for this the Italian or Evergreen variety is usually preferred. It bears clipping well, is not liable to be eaten by insects, and having only fibrous roots, it robs the ground less than any other shrub. It is one of the few plants that will thrive in the smoke of London, though it seldom produces any flowers in the closer parts after the first year. It also grows well under the drip of trees. The leaves are bitter and slightly astringent; a strong infusion of them in water, with the addition of a little red wine and honey, is an excellent gargle for the mouth and throat when they are sore, or for the gums when they become spongy, and are apt to bleed. From the pulp of the berries a rose-coloured pigment may be prepared. With the addition of alum, they dye wool and silk of a good durable green, and for this purpose must be gathered as soon as they are ripe. They continue on the shrub till spring, and in times of scarcity are eaten by different sorts of birds, particularly the bulfinch. The wood is hard, and fit for turning. It is not generally eaten by cattle. Linneus says, kine, sheep, and goats, will eat it; but horses refuse it. The Sphinx *Ligustri*, or Privet Hawk-moth, and *Phalæna Syringaria*, feed on it in the caterpillar state; and *Meloe Vesicatorius*, *Cantharides* or Blistar Beetle, is found on it. Our old English authors call it, *Prim*, *Print*, and *Primprint*, probably from its regular

appearance when clipped. The Germans, Dutch, Danes, and Swedes, call it *Liguster*; the French, *Trœne*; the Italians, *Ligustro*; in Spanish, *Alhena*; in Portuguese, *Alfena*; and in Russian, *Schost*.—This shrub is easily propagated by laying down the tender shoots in autumn. In one year's time they may be removed where they are to remain, or planted in a nursery for two or three years, where they may be trained for the purposes designed. Also, by suckers, which it sends forth in great plenty. But these are not easily kept within bounds, nor do they rise so high as those which are increased by layers. Thirdly, by cuttings, planted in the autumn on a shady border, and in a loamy soil. But the strongest and best plants are raised from seeds. Gather the berries when ripe, put them into a pot with sand, bury them in the ground, as is practised with Holly-berries and Haws. After they have laid a year in the ground, take them up, and sow them in the autumn on a border exposed to the east, where the plants will come up in the following spring. The varieties with striped leaves may be increased by budding or inarching upon the plain sort; or by laying down the branches, but they seldom shoot so fast as to produce branches proper for this purpose. Being more tender, they should have a dry soil, and a warm situation. In a rich soil, they soon lose their variegation, and become plain. The Italian or Evergreen Privet, is now generally found in the nurseries instead of the common one. It is equally hardy, and will thrive in almost any situation. It is increased in the same manner; but as it seldom produces berries here, they must be procured from Italy.

2. *Ligustrum Japonicum*; *Broad-leaved Privet*. Leaves ovate-acuminate; panicle decomposedly trichotomous; stem arboreous, very much branched, a fathom and half in height; branches opposite, roundish; panicle spreading. It flowers in June and July.—Native of Japan.

3. *Ligustrum Sinense*. Leaves lanceolate; racemes oblong, lateral, and terminating. This is a small tree, about eight feet high; flowers white, small; corolla bell-shaped.—Native of China about Canton.

Lilac. See *Syringa*.

Lilium; a genus of the class Hexandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: none. *Corolla*: six-petalled, bell-shaped, narrowed beneath; petals upright, incumbent, obtusely carinated on the back, gradually more expanding, wider, with thick reflex obtuse tips; nectary a longitudinal tubular line, engraven on each petal from the base to the middle. *Stamina*: filamenta six, awl-shaped, upright, shorter than the corolla; antheræ oblong, incumbent. *Pistil*: germen oblong, cylindric, striated with six furrows; style cylindric, length of the corolla; stigma thickish, triangular. *Pericarp*: capsule oblong, six-furrowed, with a three-cornered hollow obtuse tip, three-celled, three-valved; the valves collected by hairs, disposed in a cancellated manner. *Seeds*: numerous, incumbent, in a twin order, flat outwardly, semiobicular. *Observe*. The nectary in some is bearded, in others beardless; petals in some totally revolute, in others not so. **ESSENTIAL CHARACTER.** *Corolla*: six-petalled, bell-shaped, with a longitudinal nectareous line. *Capsule*: the valves connected by cancellated hairs.—The species are,

1. *Lilium Candidum*; *Common White Lily*. Leaves scattered; corollas bell-shaped, smooth within; bulb large, from which proceed several succulent fibres; stem stout, round, upright, usually about three feet in height; flowers large, white, terminating the stem in a cluster, on short peduncles; petals within of a beautiful shining white, on the outside rigid and less luminous. The principal varieties of this

species are, 1. With the flowers striped or blotched with purple. This is become very common; but the purple stain giving the flower a dull colour, the common white is preferred. 2. With variegated or striped leaves, or with the leaves edged with yellow. This is chiefly valued for its appearance in winter and spring: for the leaves coming out early in the autumn, spreading themselves flat on the ground, and being finely edged with a broad yellow band, make a pretty appearance during the winter and spring months. It flowers earlier than the plain sort. 3. With double flowers. This variety is of little value, because the flowers never open well, unless they are covered with glasses; nor have they any of the rich colour of the common sort. 4. With pendulous flowers; which Miller and others consider as a distinct species. It came originally from Constantinople. The stalk is much more slender; the leaves are narrower and fewer in number; the flowers are not so large, and the petals more contracted at the base; they always hang downwards.—The flowers of the Lily were formerly considered as antiepileptic and anodyne; a distilled water of them was employed as a cosmetic; and oil of lilies was supposed to possess anodyne and nervine powers: but their odorous matter, though very powerful, is totally dissipated in drying, and entirely carried off in distillation either with spirit or water, and no essential oil can be obtained from them. The roots only are now in use; they are extremely mucilaginous, and are chiefly employed in emollient and suppurating cataplasms, boiled with milk or water. Physicians, however, are generally of opinion that bread or meal poultices possess every advantage of those prepared from the lily-root. Meyrick, however, says that the root bruised and applied to hard tumors, softens and ripens them sooner than almost any other application. Made into an ointment, they take away corns, and remove the pain and inflammation arising from burns and scalds. Country people sometimes, continues he, make an oil from the flowers by infusing them in oil of olives, and apply it to any part affected with pain and inflammation with great success. It is likewise an excellent application to contracted tendons.—Native of the Levant: Linneus says, of Syria; and Thunberg, of Japan. It flowers in June and July. This plant, with all its varieties, and in short with all the plants of the genus, may easily be increased from offsets, which the bulbs of this sort send out in such great plenty, as to make it necessary to take them off every other, or at most every third year, to prevent their weakening the principal bulb. The time for removing them is the end of August, soon after the stalks decay. They will thrive in almost any soil and situation, and as they grow tall and spread, they must be allowed room, and in large borders they are very ornamental. They are so hardy that no frost injures them; and increasing very fast, are become so very common as to be little regarded, notwithstanding the great beauty of the flowers, and their rich odour, which is too powerful for many persons.

2. *Lilium Japonicum*; *Japan White Lily*. Leaves scattered, lanceolate; corollas drooping, subcampanulate; stem round, smooth, and even, two feet high; flowers terminating, reflex, and hanging down; corolla white.—Native of Japan.

3. *Lilium Catesbæi*; *Catesby's Lily*. Leaves scattered, lanceolate; corollas upright, bell-shaped; petals with claws. Of all the lilies cultivated in this country, this is the least; the whole plant, when in bloom, being frequently not more than a foot high, though it is said to grow to the height of two feet in its native soil. The stalk is terminated by one upright flower, which has no scent. It was first observed by Catesby on open moist savannas in many parts of Carolina. He says that the bulb is about the size of a walnut; that the

petals turn back in a graceful manner, and are tapering, terminating in points, and edged with small indentures; and that the whole flower is variously shaded with red, orange, and lemon colours.—It flowers in July and August; native of South Carolina. This may be raised from seeds or offsets, which, however, are not very plentifully produced, and will not grow in perfection without great care; the roots in particular are to be guarded against frost.

4. *Lilium Bulbiferum*; *Bulb-bearing or Orange Lily*. Leaves scattered; corollas bell-shaped, erect, rugged within; bulb subovate, consisting of thick white loosely imbricate scales, putting out a few thick fibres from the bottom; stem upright, a foot and half high, striated, angular; flower without scent, red-orange within, pale-orange on the outside; all the petals, from the base to beyond the middle, are rugged with little scales and apophyses, with a few black dots. There are many varieties, in size, leaves, and flowers. Mr. Miller mentions the following: 1. Orange Lily with double flowers. 2. Orange Lily with variegated leaves. 3. Smaller Orange Lily. 4. Bulb-bearing Fiery Lily. These seldom rise more than half the height of the others; the leaves are narrower; the flowers smaller, and of a brighter flame colour, few in number, and more erect. They come out a month before those of the common sort, and the stalks put out bulbs at most of the axils, which, if taken off when the plants decay, and planted, will produce plants. There are also several subordinate varieties, but not worth enumeration. The Orange Lily is found wild in Austria: it also grows in Italy, and other southern regions of Europe; in Siberia, and in Japan. This sort is grown so common, and increases so readily by offsets, that it is almost rejected. It should not, however, be excluded from large gardens, since, when properly disposed, it makes a handsome appearance while in flower. The stalks decay in September, the roots may be then transplanted, and the offsets taken off; but as it does not put out new leaves till toward spring, this may be done till near Christmas. It should be repeated once in three years. It will thrive in any soil or situation; but will be strongest in a soft, gentle, and not too moist loam. The bulb-bearing varieties may also be increased without taking up the plants, by means of the little bulbs that are put forth in plenty from the axils of the leaves. Both these sorts, with their varieties, will thrive under the shade of trees, and are therefore proper to be introduced into plantations, and on the borders of woods.

5. *Lilium Pomponium*; *Pomponian Lily*. Leaves scattered, awl-shaped; flowers turned back; corollas rolled back. This has a pretty large scaly root, from which rises an upright stalk nearly three feet high. The upper part of the stalk divides into four or five peduncles, each sustaining a single flower of a fine carmine colour, with a few dark spots scattered over it. They appear in July, and in hot seasons continue a considerable time in beauty. The peduncles are very long, so that the flowers spread out very wide.—Native of the Pyrenees, Japan, and China. This, and the four following species, may be propagated by offsets, which some produce in great plenty, but others send out very few, and are therefore more scarce. The roots may be taken up when the stalks decay, and if there be a necessity for keeping them out of the ground to remove them to a distant place, they should be wrapped in dry moss, which will preserve them for two months. The best time to replant them is at the beginning of October, but if the ground be not ready to receive them, they should be covered with dry sand or wrapped in moss, to prevent the scales from shrinking, which weakens the bulbs, and often occasions them to be mouldy and rot. The roots should be planted five or six inches deep in the ground, especially if

the soil be light and dry; but where it is moist, raise the borders five or six inches; for if the water come near the roots in winter, it will rot them; and where the soil is stiff and binding, mix a good quantity of sea-coal ashes or rough sand with it.

6. *Lilium Chalcedonicum; Scarlet Martagon Lily.* Leaves scattered, lanceolate; flowers turned back; corollas rolled back. It is from three to four feet high; the leaves are much broader than those of the preceding, and appear as if they were edged with white; they are placed very closely upon the stalks. The flowers are of a bright scarlet, and seldom more than five or six in number. It flowers late in July, and in cool seasons continues in beauty great part of August. There are some varieties of this species in the size and colour of the flowers, which are sometimes of a blood red.—Native of the Levant, and the mountains between Carniola and Carinthia. See the preceding species.

7. *Lilium Superbum; Great Yellow Martagon Lily.* Leaves scattered; flowers in a branched pyramid, turned back; corollas rolled back; stem round, very smooth and even, panicled at top, two feet high and more; branches alternate, divaricating, upright, like the stem, reflex at top, flower-bearing; one flower at the end of each branch; corollas large and handsome; petals oblong, acute, white, with large purple spots and smaller black ones from the middle to the base. See the fifth and eighth species.

8. *Lilium Martagon; Purple Martagon Lily.* Leaves in whorls; flowers turned back; corollas rolled back. This rises with a strong stalk from three to four feet high; flowers dark purple with some spots of black; they are produced in loose spikes, appear in June, and have a disagreeable odour when near, but not so offensive as the preceding; stem straight, round, shining, from a foot and half to four feet in height.—Native of the south of Europe, and of Siberia. There is a variety which flowers early in June, known in old gardens by the name of Turk's Caps. In Holland they raise a great variety of Martagons: those most commonly found in the English gardens are, 1. The Common Martagon with double flowers; 2. The White; 3. The Double White; 4. The White Spotted; 5. The Imperial; 6. The Early Scarlet; 7. The Constantinople Vermilion Martagon. The way of obtaining these and other varieties is, by sowing the seeds of the best flowers in square boxes, six inches deep, with holes bored in their bottoms, and filled with light sandy earth: the beginning of October, soon after the seeds are ripe, is the proper season. Sow them pretty thick, covering them about half an inch with light sifted earth; place the boxes where they may have the morning sun only, and refresh them with water often, if the season prove dry. In November remove them to where they may have as much sun as possible, and be screened from wind. About the beginning of April restore them to their former position: for now the young plants, which are impatient of heat, will appear; and the soil will dry too fast, if exposed to the full sun at noon. Keep them entirely free from weeds, and refresh them gently and cautiously with water in dry seasons. Let the boxes remain till the beginning of August; then prepare some beds of fresh light earth, level them, and take the earth out of the boxes with the small bulbs, and strew it equally over the beds, covering it half an inch thick with fine sifted earth. If the season prove hot and dry, shade the beds in the middle of the day, and refresh them with water.—If the following winter season be severe, cover the beds with pease-haulm, or other light covering, to keep out the frost; but this would injure the bulbs in mild weather. At the end of February, or the beginning of March, when the hard frosts are over, gently clear off the earth upon the surface of the

beds, and sift a little fresh earth over them: but in doing this, do not disturb or injure the bulbs. Keep them clear from weeds; water them gently in dry weather, and in very hot days shade them from the sun. When their leaves are quite decayed, stir the surface of the beds again; and in September sift more fresh earth over the beds. During winter and spring manage them as before directed. In September following, transplant the bulbs to a greater distance, on beds prepared as above; place them about eight inches asunder, with the buds uppermost, and four inches deep: this should be done in moist weather. The second year after being planted in these beds, the strongest bulbs will begin to flower; then place a stick wherever you observe any peculiar varieties; and when the leaves are decayed, remove these bulbs into other beds at a greater distance, or into the borders of the flower-garden; but never reject any till they have flowered two years: for frequently some will make a mean appearance the first year, and afterwards become fair handsome flowers, when they have obtained strength. When such have been selected as are worth preserving, the rest may be planted in shady outer walks, or in the borders of plantations. See the three preceding and the first species.

9. *Lilium Canadense; Canada Martagon Lily.* Leaves in whorls; flowers turned back; corollas resolute, bell-shaped; bulbs oblong and large; stems from four to five feet high; flowers large, yellow, spotted with black; they come out in the beginning of August, and, when the roots are large, in great numbers, making a fine appearance. There is a variety of it with larger and deeper-coloured flowers.—Native of Canada; observed also in Pennsylvania and Japan. See the four preceding species, and also the first species.

10. *Lilium Kamschatcense; Kamschatka Lily.* Leaves in whorls; flower erect; corolla bell-shaped; petals sessile; bulb roundish, small; stem quite simple, round, even, a foot high; flowers terminating, few, an inch and half in diameter, on very short, naked, almost upright peduncles.—Native of Kamschatka, and also of China and Cochin-china.

11. *Lilium Philadelphicum; Philadelphian Martagon Lily.* Leaves in whorls; flowers erect; corolla bell-shaped; petals with claws; root smaller than in other sorts, scaly and white; stem single, upright, nearly a foot and half high, terminated by two flowers, which stand erect upon short separate peduncles: they are shaped like those of the Bulb-bearing Fiery Lily; but the petals are narrower at their base; towards which they are marked with several dark purple spots, their general colour being a bright purple. It flowers in July, and the seeds ripen at the end of September.—Native of North America; observed also in Japan. This species growing in a small compass, and the flowers having no ill smell, is proper for the borders of small gardens. The stalks decay soon after the seeds are ripe: then is the proper time to remove the roots, which do not put out new fibres till after Christmas. The bulbs do not put out many offsets.

12. *Lilium Umbellatum.* Leaves linear, short; top-leaves verticillated, shorter than the peduncles; flowers from three to five, umbellated, erect; petals recurvo-patent, subequal, ovate-oblong, subunguiculate; the flowers are of a uniform deep scarlet colour, and are highly ornamental.—It was found upon the banks of the Missouri by Messrs. Lewis and Nuttall. Pursh conjectures it to be the same with the one figured in the *Paradisus Londinensis*, under the name of *Lilium Concolor*.

Lily, Day. See *Hemerocallis*.

Lily, Guernsey. See *Amaryllis*.

Lily, May. See *Convallaria Maialis*.

Lily, Persian. See *Fritillaria*.

Lily, Superb. See *Gloriosa*.

Lily, Thorn. See *Catesbæa*.

Lily of the Valley. See *Convallaria*.

Lily, Water. See *Nymphæa*.

Lime Tree. See *Citrus* and *Tilia*.

Limeum; a genus of the class Heptandria, order Digynia.

—GENERIC CHARACTER. *Calix*: perianth five-leaved; leaflets ovate, acuminate, keeled, membranaceous on the margin, two exterior, permanent. *Corolla*: petals five, equal, ovate, somewhat clawed, obtuse, shorter than the calix; nectary, a margin surrounding the germen, bearing the stamina. *Stamina*: filamenta seven or fewer, awl-shaped, shorter than the corolla; antheræ ovate. *Pistil*: germen globose; style parted, cylindric, shorter than the stamina; stigmas rather obtuse. *Pericarp*: none; fruit bipartite into *Seeds*: two, hemispheric, hollow, naked; according to Gærtner, shaped like a meniscus. ESSENTIAL CHARACTER. *Calix*: five-leaved; *Petals*: five, equal; *Capsule*: globular, two-celled.—The species are,

1. *Limeum Africanum*; *African Limeum*. Leaves oblong, petioled; (according to Thunberg, ovate-lanceolate, subpetioled;) stems prostrate, weak, a span long, angular, naked, perennial at the base; corymbs terminating, solitary, compound, naked, on long peduncles.—Native of the Cape of Good Hope.

2. *Limeum Incanum*; *Hoary Limeum*. Leaves ovate, with a strong midrib underneath; tomentose.—Native of the Cape of Good Hope.

3. *Limeum Ethiopicum*. Leaves linear-lanceolate.—Native of the Cape of Good Hope.

Limnœuce. See *Hippuris*.

Limodorum; a species of the class Gynandria, order Diandria.—GENERIC CHARACTER. *Calix*: spathes vague; spadix simple; perianth none. *Corolla*: petals five, ovate-oblong, about equal, spreading, the superior ones converging; nectary one-leaved, concave, foot-stalked, within the lowest petal; the length of the petals. *Stamina*: two; filamentum an oblong ascending body, the length of the corolla; antheræ two, ovate, looking forwards. *Pistil*: germen columnar, the length of the corolla, inferior; style filiform, growing to the body of the filamenta; stigma funnel-form. *Pericarp*: capsule columnar, three-valved, one-celled, gaping at the corners. *Seeds*: numerous, sawdust-like. *Observe*. Swartz says it is scarcely different from the *Serapias*, except in the indolence or scape. ESSENTIAL CHARACTER. *Nectary*: one-leaved, concave, pedicelled, within the lowest petal.—The species are,

1. *Limodorum Tuberosum*; *Tuberous-rooted Limodorum*. Flowers subspiked, bearded; root tuberous; stem a foot and half high; the number of flowers not exceeding five, dark purple.—Native of Virginia and South Carolina. From the little experience we have had of the management of this species, it appears to be scarcely hardy enough for the open border, yet not tender enough to require a stove. The first plants were produced here by planting the roots in pots filled with bog-earth, and plunging them into a tan-pit which had a gentle heat, for the purpose of raising plants or seeds, and for striking cuttings.

2. *Limodorum Altum*; *Tall Limodorum*. Flowers beardless; spikes subpanicled; root shaped like that of the true Saffron, but the outer cover of a darker brown colour: the flower-stalk arises immediately from the root, on one side of the leaves; it is naked, smooth, and of a purplish colour towards the top, nearly a foot and half high, and terminated by a loose spike of purplish red flowers on short peduncles. According to Swartz, this is the plant which Browne calls *Jamaica Salop*; and recommends the root, properly cured, as

a stomachic.—Native of the West Indies; particularly of Jamaica, in the cooler parts of the mountains. This and all the following species are much too tender to thrive in the open air of England, and seldom flower even in a green-house: they are therefore kept in the tan-bed in winter; and if in summer the pots be plunged in a tan-bed under a deep frame, the plants will thrive, and flower strongly. They are propagated by offsets from the roots, which are sent out pretty freely while the roots are in vigour. They should be taken off and transplanted, at the time when the plant is most destitute of leaves; and must have a soft loamy soil, with but little watering, especially in winter.

3. *Limodorum Tankervilleæ*; *Chinese Limodorum*. Flowers beardless, in racemes. It flowers in March and April.—Native of China. See the preceding.

4. *Limodorum Utriculatum*. Root tuberous; root-leaves twin-sheathed; radical sheath inflated; scape sheathed; flowers sessile.—Native of Jamaica and St. Domingo. See the second species.

5. *Limodorum Gentianoides*. Root tuberous; leaflets stem-sheathed; flowers peduncled.—Native of Jamaica. See the second species.

6. *Limodorum Striatum*. Scape angular, smooth; leaves ensiform, nerved; petals lanceolate, with an oblong flat lip. See *Epidendrum Striatum*.

7. *Limodorum Ensatum*. Scape round, even; leaves ensiform, striated; petals lanceolate; lip recurved, broader.—Native of China and Japan. See *Epidendrum Ensifolium*.

8. *Limodorum Falcatum*. Horn filiform, very long; leaves ensiform, channelled, sickled; scape upright, smooth, shorter than the leaves; flowers in spikes, terminating.—Native of Japan. See the second species.

9. *Limodorum Monile*. Scape round, striated, jointed like a necklace, simple; leaves linear, simple. See *Epidendrum Moniliforme*. It is not parasitical; but grows on walls, and in hedges.

10. *Limodorum Virens*. Root scaly; scape branched, spotted; bractes acute; flowers remote, greenish yellow; bulbs many, connected near the base, conical, pointed; scape axillary, erect, often branched, from one to two feet high, round, smooth, coloured with purple spots; flowers striated; petals nearly equal, erect or ascending.—Native of Coromandel, on dry uncultivated ground; flowering during the dry season. See the second species.

11. *Limodorum Recurvum*. Root tuberous; scape bending, nodding, shorter than the leaves; leaves broad-lanceolate, five-nerved; spike globular, nodding; bulbs striated, nearly round, surrounded with one or two rings, and having many thick fleshy fibres from their lower parts; stem from the side or base of the bulb; flowers numerous, crowded, white, with a small tinge of yellow.—Native of Coromandel, in moist valleys, among the hills; flowering at the beginning of the rainy season. See the second species.

12. *Limodorum Nutans*. Root tuberous; scape arched, longer than the leaves, ovate, five-nerved; spike oblong, pendulous. This differs from the preceding, in having the bulbs smooth, the leaves oval, the scape longer than the leaves, the spike oblong and pendulous, with the flowers at some distance from one another, of a beautiful rose-colour, and the under lip of the nectary sharp-pointed.—Native of Coromandel; flowering as the preceding. See the second species.

13. *Limodorum Aphyllum*. Plant without leaves; root fibrous; flowers solitary, naked, sessile; stems perennial, several, most simple, spreading or pendulous, as the situation admits; flowers generally issuing single from the joints of the stems.—Native of Coromandel, but very rare, on dry rocky

hills; flowering in the beginning of the hot season. See the second species.

Limonia; a genus of the class Decandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, three or five-cleft, acute, very small, permanent. *Corolla*: petals three to five, oblong, obtuse, upright, spreading at the tip. *Stamina*: filamenta six to ten, awl-shaped, upright, shorter than the corolla; antheræ linear, upright. *Pistil*: germen oblong, superior; style cylindric, length of the stamina; stigma headed, flat. *Pericarp*: berry ovate or subglobose, three-celled; partitions membranaceous. *Seeds*: solitary, ovate. ESSENTIAL CHARACTER. *Calix*: five-parted. *Petals*: five. *Berry*: three-celled. *Seeds*: solitary.—The species are,

1. *Limonia Monophylla*; *Simple-leaved Limonia*. Leaves simple; spines solitary; trunk irregular, with a smooth greenish ash-coloured bark; branches numerous, very irregular; racemes short; corolla four or five-petalled.—Native of Coromandel, in the forests on the coasts, where it grows to a small tree, though oftener found in the state of a large shrub.

2. *Limonia Lucida*. Unarmed: leaves simple; peduncles axillary.—Native of the Island of Mallicolla in the South Seas.

3. *Limonia Trifoliata*; *Three-leaved Limonia*. Leaves ternate; spines in pairs; spines stipular, longer than the petiole. This has the appearance of an orange-tree, with flexuose branches. Jussieu says the whole tree is smooth, the height of a man in the stove, with a trunk the thickness of a human arm, covered with a brownish ash-coloured bark, very much branched; the branchlets alternate, spreading; flowers sweet-smelling, on very short peduncles, axillary, in pairs, or three together, slowly succeeding each other; corolla and filamenta white; fruit red, very soft, the size of a hazel-nut; pulp colourless, very sweet, with a slight taste of turpentine.—It is a native both of China and Cochinchina, where it is much cultivated both for its beauty and fragrance, as well as the pliancy of its branches. Burman says it is also a native of Java.

4. *Limonia Pentaphylla*; *Five-leaved Limonia*. Unarmed: leaves commonly quinately; leaflets oblong, entire; trunk scarcely any, with an ash-coloured bark; branches numerous, nearly erect; flowers white, very fragrant.—This is an elegant fragrant shrub, very common in most uncultivated lands in Coromandel; but chiefly under large trees, where birds have dropped the seeds: it flowers there all the year. The whole plant, when drying in the shade, diffuses a pleasant permanent scent; the flowers are exquisitely fragrant; and birds eat the berries greedily.

5. *Limonia Acidissima*. Leaves pinnate; spines solitary. This tree is said to attain the height of thirty feet, with a trunk ten inches in diameter: the leaves and fruit have the smell of Anise.—Native of the East Indies.

6. *Limonia Arborea*. Stem arboreous, unarmed; leaves quinately; leaflets linear, serrate. The berries are eaten by birds; and the flowers are equally fragrant with those of the fourth sort. These two agree in habit: the serrate leaves are the chief distinction.—Native of the mountainous parts of the Circars, where it grows to a middle-sized tree, with a large branching head.

7. *Limonia Crenulata*. Leaves alternate, fascicled; leaflets two or three pairs, with broad-winged petioles; spines solitary; flowers white, small, fragrant, collected in small umbels or racemes, over various parts of the branchlets.—Native of Coromandel, on the low lands near the coast. It is there a shrub, but in the mountains it grows to a middle-sized tree; flowering in the hot season.

Limosella; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, five-cleft, upright, sharp, permanent. *Corolla*: one-petalled, bell-shaped, upright, equal, five-cleft, acute, small; divisions spreading. *Stamina*: filamenta four, upright; of which two are approximated to the same side, shorter than the corolla; antheræ simple. *Pistil*: germen oblong, obtuse, two-celled; style simple, length of the stamina, declinate; stigma globose. *Pericarp*: capsule ovate, half involved by the calix, one-celled, divided below by the partition, two-valved. *Seeds*: very many, oval; receptacle ovate, large. ESSENTIAL CHARACTER. *Calix*: five-cleft. *Corolla*: five-cleft, equal. *Stamina*: approximating by pairs. *Capsule*: one-celled, two-valved, many-seeded.—The species are,

1. *Limosella Aquatica*; *Common Mudwort*, or *Bastard Plantain*. Leaves lanceolate; root annual, throwing out naked cylindrical prostrate runners, which take root at their extremities and form new plants; flowers small, radical, on simple flower-stalks, which become inflexed, as the fruit ripens.—Native of most parts of Europe, in muddy and gravelly places liable to be flooded, and where water has stood during the winter. It flowers from July to September.

2. *Limosella Diandra*. Leaves sublinear. This has the same habit as the preceding, but is only one-fourth of the size: hence it is one of the smallest plants we know. It increases by very short runners.—Found by Koenig on the coast at the Cape of Good Hope.

Linconia; a genus of the class Pentandria, order Digynia.—GENERIC CHARACTER. *Calix*: perianth inferior, four-leaved; leaflets ovate, permanent; the inferior opposite pair shorter. *Corolla*: petals five, lanceolate, sessile, upright; nectary a dell impressed on the bottom of the petal, begirt beneath by the margin. *Stamina*: filamenta five, awl-shaped, margined upright, middling; antheræ obtuse, sagittated with nutant gaping auricles. *Pistil*: germen half inferior, with respect to the corolla; with respect to the calix, superior; styles two, filiform, striated; stigmas simple. *Pericarp*: capsule two-celled. *Seeds*: two. *Observe*. The perianth might perhaps be taken for bractes; and then the flower would be entirely superior. ESSENTIAL CHARACTER. *Petals*: five, with a nectareous excavation at the base; capsule two-celled.—The only known species is,

1. *Linconia Alopecuroidea*. Leaves scattered in a sort of whorl, five or six together; subpetioled, linear, three-sided, stiffish, shining, an inch long, rugged at the angles; the uppermost ciliate. This is a shrub with wand-like branches, which are few in number, and determinate, irregular from the base of the fallen leaves, as in the fir-tree; flowers at the ends of the branches, not however in bundles, but separate, lateral, sessile, the length of the leaves; corollas tenacious, flesh-coloured, or white.—Native of the Cape of Good Hope, in watery places among the mountains.

Lindera; a genus of the class Hexandria, order Monogynia.—GENERIC CHARACTER. *Calix*: none. *Corolla*: petals six, ovate, obtuse. *Stamina*: filamenta six, many times shorter than the corolla; antheræ minute. *Pistil*: germen ovate, smooth, superior; style upright, rather shorter than the corolla; stigmas two, reflex. *Pericarp*: capsule two-celled. *Seeds*: undescribed. ESSENTIAL CHARACTER. *Corolla*: six-petalled.—The only known species is,

1. *Lindera Umbellata*. Leaves aggregate at the ends of the branchlets, petioled, oblong, acute, entire, above green and smooth, underneath pale and villous, an inch long; petioles scarcely a line in length, villous above; stem shrubby, loose; branches and branchlets alternate, flexuose, smooth, spreading very much; flowers terminating in a simple many-

flowered umbel; peduncles a little hairy, unguicular; pedicels tomentose about half the length. The Japanese use the wood for making soft brushes to clean their teeth with.—Native of Japan.

Lindernia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth five-parted; divisions linear, sharp, permanent. *Corolla*: one-petalled, ringent, two-lipped; under lip very short, concave, emarginated; lower lip upright, three-cleft; the middle one rather larger. *Stamina*: filamenta four, twin; the superior ones simple; the two inferior ascending, with a terminal upright tooth; antheræ twin, the inferior ones sublateral. *Pistil*: germen ovate; style filiform; stigma emarginated. *Pericarp*: capsule oval, one-celled, two-valved. *Seeds*: numerous. *Receptacle*: cylindric. ESSENTIAL CHARACTER. *Calix*: five-parted. *Corolla*: ringent, with the upper lip very short. *Stamina*: the two lower with a terminating tooth, and a sublateral antheræ. *Capsule*: one-celled.—The species are,

1. *Lindernia Pyxidaria*. Leaves sessile, quite entire; peduncles solitary; root annual; stem smooth, square, brittle, sometimes branched, and putting forth runners; flowers axillary, solitary, on a long slender peduncle; corolla pale blue.—Native of Virginia, in watery and boggy places; flowering in July and August. Hence it has migrated into Europe; and is now found in similar situations in Alsace and Piedmont.

2. *Lindernia Dianthera*. Leaves petioled, ovate, roundish, subserrate; stem creeping.—Annual, and a native of St. Domingo.

3. *Lindernia Japonica*. Leaves obovate, toothed, the lowest petioled; root annual; stem herbaceous, branched, weak; branches alternate, somewhat villose, from an inch to a span in length; flowers at the ends of the branches in racemes; corollas rufescent.—Native of Japan.

Linnæa; (so named by Gronovius, in honour of the illustrious Carl von Linné or Linnæus, a native of Sweden, and the prince of botanists;) a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth double. *Perianth of the fruit*: inferior, four-leaved; the two opposite leaflets very small, acute; the remaining two elliptic, concave, upright, hispid, embracing the germen, converging, permanent. *Perianth of the flower*: superior, one-leaved, five-parted, upright, narrow, sharp, equal. *Corolla*: one-petalled, bell-shaped, half five-cleft, obtuse, subequal, twice as large as the calix of the flower. *Stamina*: filamenta four, awl-shaped, inserted into the bottom of the corolla; of which two are very small, the two nearest longer; shorter than the corolla; antheræ compressed, versatile. *Pistil*: germen roundish, inferior; style filiform, straight, length of the corolla, declinate; stigma globose. *Pericarp*: berry juiceless, ovate, three-celled, covered by the hispid glutinous perianth of the fruit, deciduous. *Seeds*: two, roundish. ESSENTIAL CHARACTER. *Calix*: double, of the fruit two-leaved, of the flower five-parted, superior. *Corolla*: bell-shaped. *Berry*: dry, three-celled.—The only known species is,

1. *Linnæa Borealis*; *Two-flowered Linnæa*. Root perennial, fibrous; stems filiform, from three to six feet long, loose, creeping, round, perennial, ferruginous, with a few white hairs scattered over them; leaves opposite, roundish, ovate, spreading, attenuated into the petioles; branches alternate, simple, upright, with six or eight leaves on them; peduncles terminating the older branches, solitary, a finger's length, upright, having different hairs scattered over them, some very minute, reflex-pellucid, others spreading, secreting a glutinous juice; corolla turbinate; three times as long as the

calix, smooth and white on the outside, having a few hairs scattered over it within, with blood-red veins within the cavity, which are yellow on the lower side. The smell of the flowers approaches to that of *Ulmaria*, or Meadow Sweet; and is so strong during the night, as to discover this little plant at a considerable distance. In Sweden, where the plant is common, an infusion of the leaves in milk is employed in the rheumatism. In Norway they cure the itch with a decoction of it. And in Ostrobothnia they apply it in a cataplasm, or by fomentation, to disorders of the feet in sheep.—Native of Sweden, Norway, Switzerland, Silesia, Italy, Russia, Siberia, and Canada, in large forests and woods, especially where moss abounds; and flowers in June. It has been discovered in an old fir-wood at Mearns, near Aberdeen in Scotland.

Linociera; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth very small, four-toothed, obtuse, permanent. *Corolla*: petals four, equal, linear, channelled, upright, spreading at top, many times longer than the calix. *Stamina*: filamenta two, very short, rather broad; antheræ linear, two-furrowed, length of the corolla, upright, each adhering slightly to the other side of the two petals. *Pistil*: germen superior, ovate, four-cornered; style short; stigma oblong, two-cleft. *Pericarp*: berry ovate, sharp-pointed, two-celled. *Seeds*: solitary, oblong. ESSENTIAL CHARACTER. *Calix*: four-toothed. *Corolla*: four-petalled. *Antheræ*: connecting two opposite petals at the base. *Berry*: two-celled.—Dr. Smith suggests, that by examining the fruit in an early state, it will be found that the *Linociera* of Schreber is not distinct from *Chionanthus*. See *Chionanthus*. There is but one species, *Linociera Ligustrina*, a native of open places in the West Indies.

Linum; a genus of the class Pentandria, order Pentagynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, lanceolate, upright, small, permanent. *Corolla*: funnel-form. *Petals*: five, oblong, gradually wider above, obtuse, more spreading, large. *Stamina*: filamenta five, awl-shaped, upright, length of the calix; (also five rudimenta, alternating;) antheræ simple, arrowed. *Pistil*: germen ovate; styles five, filiform, upright, length of the stamina; stigmas simple, reflex. *Pericarp*: capsule globose, rudely pentagonal, ten-valved, gaping at the tip; partitions membranaceous, very thin, connecting the valves. *Seeds*: solitary, ovate-flattish, acuminate, smooth. *Observe*. In many species, if not in all, the filamenta are united at the base: in the twenty-third, a fifth part is excluded. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Petals*: five. *Capsule*: ten-valved, ten-celled. *Seeds*: solitary.—The species are,

* *With alternate Leaves*.

1. *Linum Usitatissimum*; *Common Flax*. Calices and capsules mucronate; petals crenate; leaves lanceolate; stem generally solitary; roots annual, simple, fibrous, pale brown; stem upright, eighteen inches, two feet, and even more, in height, round, smooth, leafy, branched only at top; flowers large, growing in a panicle, on round smooth peduncles; petals wedge-shaped, deciduous, sky-blue, streaked with deeper-coloured lines, white at the claws, and somewhat gnawed at the tip.—Flax is now found wild in many parts of Europe, in corn-fields. In England we cannot assert it to be aboriginal, though it is said to be very common in the western counties, not only in corn-fields, but in pastures and on downs. It flowers in June and July. The plants of Flax, when crowded together in cultivation, rise only a foot and half high, with a slender unbranched stalk; yet when they are allowed room, will rise more than two feet high, and put out two or three side-branches towards the top, especially in

a good soil. There is a dwarf variety, which has stronger and shorter stalks, branching out more, the leaves broader, the flowers larger, with the petals indented at the extremity, the seed-vessels much larger, and the peduncles longer. This valuable plant is supposed to have been derived originally from those parts of Egypt which are exposed to the inundations. In the earliest record we have, *Exodus ix. 31.* flax is mentioned as a plant cultivated in that country; on which account antiquaries have been surprised to find the vestments of mummies made of cotton. It is highly probable, however, that mankind made thread of cotton before the use of flax was discovered; the former being produced in a state ready for spinning, whereas the latter requires a long process before it can be brought to that state. It is difficult, or perhaps impossible, to determine when the culture of flax was first introduced into this country. In the simplicity of ancient times, when families provided within themselves most of the necessities and conveniences of life, every garden supplied a proper quantity of hemp and flax. The macerating or steeping necessary to separate the fibres, by rotting the rest of the stalk, was found to render water so offensive, that by the 33rd of Henry VIII. it was enacted that no person should water any Hemp or Flax, in any river or stream, or in any common pond, where beasts are used to be watered. The seeds of flax, called Linseed, yield, by expression only, a large proportion of oil, which is an excellent pectoral, as is likewise the mucilaginous infusion. The oil is of a healing balsamic nature, and very useful in coughs, attended with spitting of blood, in colics, and obstinate costiveness. Outwardly applied, it softens and eases pain. The seeds in substance are used as poultices, to soften and ripen inflammatory tumors, and are well adapted for that purpose. The infusion is likewise a good medicine in the strangury, heat of urine, thin sharp deflections on the lungs, and other similar disorders. An ounce of the seeds is a sufficient quantity for a quart of water; for if added in a larger quantity, they render the liquor disagreeably slimy. After the oil is expressed from the seeds, the remaining farinaceous part, called oil-cake, is given to oxen, who soon grow fat upon it. This oil differs in several respects from other expressed oils: it does not congeal in winter, nor does it form a solid soap with fixed alkaline salts, and it acts more powerfully as a menstruum upon sulphureous bodies. When heat is applied during the expression, it acquires a yellowish colour, and a peculiar smell. In this state it is used by painters and varnishers. It is well known that the fibres of the stem are manufactured into linen, and that this linen, when worn to rags, is made into paper. Flax in German is called *Flacks*, or *Lein*; in Dutch, *Vlasch*; in Danish, *Hörr* or *Hürr*; in Norwegian, *Lün*; in Swedish and French, *Lin*; in Italian and Spanish, *Lino*; in Portuguese, *Linho*; in Russian, Polish, and all the languages from the Sclavonian, *Len*, or *Lan*. All the Europeans, except the Danes, use *Lin*, when speaking of the seed.—Flax requires a rich dry soil, or fat sandy loam, particularly that which is formed from the sediment of great rivers; hence old grass-land of this description is its most proper matrix. It is, however, not unfrequently sown on arable land; and, when the soil is in heart, dry, friable, and clean, with good success. Much depends on the state of the soil at the time of sowing. It should neither be wet nor dry, and the surface ought to be made as fine as that of a garden bed. For the crop should all rise together, and the surface should be evenly seeded. If the plants come up at several times, or if by accident or mismanagement they be thin upon the ground, the crop is irreparably injured. This will be the case in a severe season of drought, or when spring frosts are severe,

or when the crop is attacked by a small white slug; or when the ground being full of clods, the seeds are not evenly dispersed, and not being able to pierce the clods, come up in circles round them, leaving vacancies in the centre favouring their early branching, than which nothing is more detrimental to the crop, the goodness of it depending much on its running up with a single stalk, for wherever it branches, the fibres terminate, and they are worked off in dressing. If the crop be intended for thread of the first quality, the time of pulling it is when the seeds are formed; but if they be suffered to ripen, the advantage gained by the seed is balanced by the inferior quality of the flax, the filamenta being harsh, and the cloth made from them not taking a good colour in whitening. It is also a great exhauster of the soil, when it stands for the seed to ripen. The flax crop interferes with harvest, and therefore ought to be confined to rich grass-land districts, where harvest is a secondary object, and where exhaustion may be rather favourable than hurtful to succeeding arable crops, by checking the too great rankness of the rich fresh-broken ground. It has been strongly recommended, instead of steeping the flax in ponds or other cold water, to separate the *boon* or pulp of the stalk, from the *harle* or fibrous part, which constitutes the flax, by boiling it in water. If this process should be found to answer as well as the common one, much time and labour would be saved, and the air and waters would not be poisoned, as they now are where flax and hemp are steeped. The flax would also in all probability be of a finer colour, and the operation of bleaching safer and less tedious; but whether the strength of the thread would be improved or diminished, experience only can decide.—The common mode of cultivating flax is as follows. In order to have the ground as clear from weeds as possible, it should be fallowed two winters, and one summer, and harrowed between each ploughing, particularly in summer, to destroy the young weeds soon after they appear. This will also break the clods by separating their parts, so that they will fall to pieces on being stirred. If the land should require dung, that ought not to be laid on till the last ploughing, when it must be buried in the ground: but this dung should be clear from seeds of weeds, which it may be by laying it in a heap, and fermenting it well. Just before the season for sowing the seed, the land is well ploughed, and laid very even. The seeds are sown at the end of March, or the beginning of April, when the weather is mild and warm. The seed is sown broad-cast, two to three bushels to an acre; but from many repeated trials, says Mr. Miller, I have found it a much better method to sow the seed in drills, at about ten inches' distance from each other, by which half the quantity of seed usually sown will produce a greater crop; and when the flax is thus sown, the seed may be easily hoed to destroy the weeds: if this operation be twice repeated in dry weather, it will keep the ground clean till the flax is ripe; this may be done at half the expense which hand-weeding will cost, and will not tread down the plants nor harden the ground, which by the other methods is always done; and it is absolutely necessary to keep the flax clean from weeds, otherwise they will overbear and spoil the crop. Towards the end of August, or the beginning of September, the flax will begin to ripen, and it must not stand to be over-ripe, but be pulled up by the roots as soon as the heads begin to change brown, and hang downwards, otherwise the seeds will soon scatter and be lost; so that the pluckers must be nimble in tying up the plants in handfuls, and setting them upright, till they are dry enough to be housed. If the flax be pulled when it first begins to flower, the thread will be whiter, but then the seed will be lost. The thread, however, will be stronger when

the flax is left till the seed is ripe, provided it does not stand too long; but the colour of it will not be so good. Some recommend sheep-feeding with the flax, when it is a good height, and affirm that they will eat the weeds and grass, and do the flax good; and that if they should beat it down, that it will rise again with the next rain. But this is a very wrong practice, for if the sheep gnaw the flax, it will shoot up very weak, and never attain to half the size it would have done if it had not been cropped; and if the sheep like the crop better than the weeds, they will devour that, and leave the weeds untouched.

2. *Linum Perenne*; *Perennial Flax*. Calices and capsules blunt; leaves lanceolate, quite entire. From its perennial root arise three or four inclining stalks, having short narrow leaves towards their base, but scarcely any about the top. The flowers are produced at the ends of the stalks, sitting very close; they are of a delicate texture, and very elegant blue colour. Mr. Miller distinguishes the upright Siberian plants. The stems of this are strong, in number according to the size of the root, in height from three to five feet according to the soil; they divide into several branches at top. The flowers are large, of a fine blue, appearing in June, and are succeeded by obtuse seed-vessels, ripening in September. He recommends the cultivating it for use; being perennial, earlier, more productive, and yielding a stronger though not so fine a thread.—Native of Cambridgeshire, Norfolk, Suffolk, and Northamptonshire, on calcareous pastures. This flax has been tried, and answers very well for making common strong linen, but the thread is not so fine or white as that which is produced from the common sort; but as the roots of this will continue many years, it will require little other culture, but to keep it clean from weeds, which cannot well be done, unless the seeds be sown in drills, that the ground may be constantly kept hoed to destroy the weeds when young. This sort must have the stalks cut off close to the ground when ripe, and then managed in the same way as the common sort; but it seldom produces more than three crops that will pay for standing.

3. *Linum Monogynum*; *One-styled Flax*. Calices acute; leaves linear-lanceolate, even; stem round, shrubby, and branched at the base; flowers one-styled.—Native of New Zealand, in Queen Charlotte's Sound.

4. *Linum Viscosum*; *Clammy Flax*. Leaves lanceolate, hairy, five-nerved; root woody, perennial.—Native of Germany.

5. *Linum Hirsutum*; *Hairy Flax*. Calices hirsute, acuminate, sessile, alternate; branch-leaves opposite; root woody, perennial; stems round, simple, hairy, from a foot to two feet in height; flowers on very short peduncles; petals blue, marked with lines.—Native of Austria and Hungary.

6. *Linum Narbonnense*; *Narbonne Flax*. Calix acuminate; leaves lanceolate, stiff, rugged, acuminate; stem round, branched at the base; filamenta connate; root perennial; stem from a foot to eighteen inches high, branching out almost to the bottom into many long slender branches; flowers at the ends of the branches.—Native of the south of France, Switzerland, and Italy. It flowers from May to July.

7. *Linum Reflexum*; *Reflex-leaved Flax*. Calices acuminate; leaves ovate-lanceolate, acuminate, reflex, even; filamenta connate; stem a foot high, round, woody, branched from the base; flowers in a sort of umbel, large, blue. It flowers in July.—Native of the south of Europe.

8. *Linum Tenuifolium*; *Fine-leaved Flax*. Calices acuminate; leaves linear, setaceous, rugged backwards; root perennial, woody, branching; stems ascending at the base; flowers in a sort of panicle, peduncled; petals rose-coloured,

purple, or white, nearly twice as long as the calix.—Native of the south of Europe.

9. *Linum Angustifolium*; *Narrow-leaved Flax*. Calix obsoletely three-nerved; leaflets and capsule acuminate; leaves linear-lanceolate, three-nerved; stems numerous, a little inclined. This is very much allied to the first species.—Native of Cornwall and Devonshire, in dry sandy pastures, especially near the sea. It is also found at Dorsham in Suffolk; Minster in the isle of Sheppey; at Beacon Hill, and Deal in Kent; and near Hastings in Sussex.

10. *Linum Gallicum*; *Annual Yellow Flax*. Calices awl-shaped, acute; leaves linear-lanceolate; peduncles of the panicle two-flowered; flowers subsessile; root annual; flowers yellow.—Native of the south of France.

11. *Linum Maritimum*; *Sea Flax*. Calices ovate-acute, awnless; leaves lanceolate, the lower ones opposite; root perennial; stems herbaceous, round, almost upright, glaucous; petals yellow. It flowers in July and August.—Native of the south of Europe and the Levant.

12. *Linum Alpinum*; *Alpine Flax*. Calices rounded, blunt; leaves linear, sharpish; stems declinate; root perennial, branched; stems herbaceous, simple, half a foot or more in length; flowers peduncled, large; petals pale blue.—Native of Austria, Piedmont, Dauphiny, and Silesia.

13. *Linum Austriacum*; *Austrian Flax*. Calices rounded, blunt; leaves linear, sharp, straightish; root perennial, woody; stems herbaceous, annual, from six to eighteen inches long; peduncles one-flowered; petals white, purplish, blue or violet, with darker lines and a yellow claw. It flowers in June and July.—Native of Austria and the Palatinate.

14. *Linum Virginianum*; *Virginian Flax*. Calices acute, alternate; capsules awnless; panicle difform; leaves lanceolate; root-leaves ovate; stem filiform, a foot high, paniced; flowers on very short peduncles; corollas yellow.—Native of Virginia and Pennsylvania.

15. *Linum Flavum*; *Perennial Yellow Flax*. Calices subserrate-rugged, lanceolate, subsessile; panicle with dichotomous branches; root perennial, woody; stems herbaceous, upright, from six to eighteen inches high; flowers elegant, upright, on short peduncles, at the end of the branches, and at the divisions of them. The flowers open most in the morning, when the sun shines, and continue in succession during June, July, and part of August.

16. *Linum Strictum*; *Upright Flax*. Calices awl-shaped; leaves lanceolate, stiff, mucronate, rugged at the edge. This is an annual plant, with an upright stalk nearly a foot and half high.—Native of the south of France, Spain, and Sicily.

17. *Linum Suffruticosum*; *Shrubby Flax*. Leaves linear, acute, rugged; stems suffruticose. This has a shrubby stalk, a foot high, sending out several branches; flowers at the ends of the branches, erect, on long slender peduncles; petals large, entire, white, but before the flowers open pale yellow. They appear in July, but the seeds seldom ripen in England.—Native of Spain, about Aranjuez, but common in the kingdom of Valencia.

18. *Linum Arboreum*; *Tree Flax*. Leaves wedge-shaped; stems arborescent. This beautiful species forms (if not a tree, as its name imports,) a shrub of the height of several feet. It begins to flower in March, and continues flowering to the close of summer, but has not yet produced seeds in England.—Native of the island of Candia.

19. *Linum Campanulatum*. The base of the leaves dotted-glandular on both sides; stem simple, a finger long.—Native of the south of France, and of Russia.

** *With opposite leaves.*

20. *Linum Africanum*; *African Flax*. Leaves linear-lan-

ceolate; flowers terminating, peduncled; stem suffruticose, stiff, a foot high, round, with simple branches; flowers in a terminating umbel; petals yellow, with villose claws, and turning tawny. It flowers in June and July.—Native of Africa.

21. *Linum Nodiflorum*; *Knotted Flax*. Floriferous leaves opposite, lanceolate; flowers alternate, sessile; calices the length of the leaves; stem angular, even, bifid, or trifid; root perennial; corolla yellow.—Native of Italy.

22. *Linum Catharticum*; *Purging Flax*. Leaves ovate-lanceolate; stem dichotomous; corollas acute; root annual, very small; flowers terminating, solitary, pendulous before they open, then erect; petals white. It sometimes varies with four stamina and four styles. This small delicate species of flax, called also in some places *Mill Mountain*, is very common throughout England in dry hilly pastures, and flowers from the end of May to August. Gerarde celebrates this little plant as a purge. His receipt is a handful of the herb infused in a pint of warm white wine all night, and taken in the morning. Lewis prescribes an infusion in water or whey of a handful of the fresh leaves, or a drachm in substance of them dried. Dr. Withering recommends an infusion of two drachms or more of the dried herb, as an excellent purge in many obstinate rheumatisms; and adds, that it frequently acts as a diuretic.—Native of most parts of Europe.

23. *Linum Radiola*; *Least Flax*, or *All-seed*. Stem dichotomous; flowers four-stamined, four-styled; root annual; leaves sessile, ovate, acuminate; flowers upright, solitary, small, white. With us it is called *All-seed* and *Least Rupture Wort*, and is found on moist sandy heaths; flowering in July and August.—Native of many parts of Europe.

24. *Linum Quadrifolia*; *Four-leaved Flax*. Leaves in fours.—Native of the Cape of Good Hope.

25. *Linum Verticillatum*; *Whorl-leaved Flax*. Leaves in whorls. Annual; stems round, branched, not more than a foot high; flowers violet or blue gray.—Native of Italy, near Rome.

26. *Linum Lewisii*. Leaves of the calix ovate-acuminate; petals cuneate, rounded at the top; leaves lanceolate-linear, mucronate; stems lofty, numerous.—Found by Lewis in the valleys of the Rocky Mountains, and on the banks of the Missouri. The flowers are large and blue; it is a very good perennial; and Pursh thinks it would be useful if cultivated.

27. *Linum Rigidum*. Leaves of the calix ovate, acuminate, three-nerved, ciliate; petals oblong, very narrow; leaves stiffly erect, linear, short; flowers sulphur-yellow coloured.—This plant was discovered on the banks of the Missouri by Mr. Thomas Nuttall, to whose unwearied diligence the delightful science of Botany is already greatly indebted.

Lion's Foot. See *Catananche*.

Lion's Leaf. See *Leontice*.

Lion's Tail. See *Phlomis Leonurus*.

Liparia; a genus of the class Diadelphia, order Decandria.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, very obtuse at the base, half five-cleft, acute; the lowest division very long, elliptic, petal-like. *Corolla*: papilionaceous, without processes of the keel or wing; standard oblong, con-duplicated, straight, the sides reflex; wings oblong, straight, narrower at the base, two-lobed at the lower margin. *Keel*: lanceolate, subascending, two-parted at the base. *Stamina*: filamenta diadelphous, simple and nine-parted, filiform, three shorter than the rest; antheræ ovate. *Pistil*: germen sessile, very short; style filiform, middling; stigma simple. *Pericarp*: legume ovate. *Seeds*: few. **ESSENTIAL CHARACTER.** *Calix*: five-cleft, with the lowest segment elongated.

Corolla: wings two-lobed below. *Stamina*: the larger, with three shorter teeth. *Legume*: ovate. For their propagation and culture, see *Borbonia*.—The species are,

1. *Liparia Sphærica*; *Globe-flowered Liparia*. Flowers in heads; leaves lanceolate, nerved, smooth; stem four feet high, stout, smooth and even; corolla tawny. The manner in which the wings wrap round each other before the flower, which is remarkably handsome, opens, is very singular; head terminating.—Native of the Cape of Good Hope.

2. *Liparia Graminifolia*; *Grass-leaved Liparia*. Flowers in heads; leaves linear, alternate, acute, sessile; calices villose; stem shrubby, determinately branched, smooth and even, angular; head made up of a raceme; corolla yellow.—Native of the Cape of Good Hope.

3. *Liparia Umbellata*; *Umbelled Liparia*. Flowers umbelled; leaves lanceolate, smooth and even; corollas smooth; calices and bractes hairy. It is the same with *Borbonia Lævigata*, which see.

4. *Liparia Villosa*; *Woolly Liparia*. Flowers in heads; leaves ovate-acute, villose; branches round; corolla red.—Native of the Cape of Good Hope.

5. *Liparia Sericea*; *Silky Liparia*. Flowers subspiked, axillary; leaves oblong-ovate, acute, villose. Allied to the preceding.—Native of the Cape of Good Hope.

Lippia; a genus of the class Didynamia, order Angiospermia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, compressed, four-toothed, bivalved when mature; valves membranaceous, acuminate, keeled, upright, permanent. *Corolla*: one-petalled, unequal; border four-cleft; divisions rounded, the inferior and superior one larger, the superior erect. *Stamina*: filamenta four, shorter than the corolla, two of them longer than the others; antheræ simple. *Pistil*: germen ovate, compressed, flat; style filiform, of the situation and length of the stamina; stigma oblique. *Pericarp*: none; valves of the calix the seeds. *Seeds*: solitary, oblong. *Observe*. Several fructifications are collected into a little head. **ESSENTIAL CHARACTER.** *Calix*: four-toothed, roundish, upright, compressed, membranaceous. *Capsule*: one-celled, two-valved, two-seeded, straight. *Seed*: two-celled.—The species are,

1. *Lippia Americana*. Heads pyramidal; height sixteen or eighteen feet, with a rough bark; branches and leaves in pairs; peduncles axillary, sustaining many pyramidal scaly heads, about the size of a large gray pea, in which are many small yellow flowers between the scales.—Found at La Vera Cruz. These shrubs, being natives of the continent and islands of the West Indies, must be preserved in a bark-stove. The seeds should be sown on a hot-bed, and the plants treated as other shrubby plants from the same country; by keeping them always in the stove, plunged in the bark-bed, and to refresh them frequently with water. In winter they must be watered more sparingly, and be kept in a moderate degree of warmth; otherwise they will not live through the winter, especially when young; but when they have acquired strength, they may be preserved with a less share of warmth. As the plants advance in their growth, shift them into larger pots; but this should not be too often repeated. Once every spring will be sufficient, for these and many other exotic plants do not thrive so well when frequently removed, as when they are permitted to fill the pots with their roots. Shift them in April; at which time the tan of the hot-bed should be stirred, and fresh tan mixed with it, to increase the heat. The earth in which these plants are placed should be light and fresh, but not too rich.

2. *Lippia Hemisphærica*. Heads hemispherical. This is

a shrub ten feet high, the whole odoriferous and aromatic; flowers small; corolla white.—Native of Carthage, in New Spain.

3. *Lippia Ovata*. Heads ovate; leaves linear, quite entire.—Native place unknown.

4. *Lippia Hirsuta*. Hirsute: leaves oblong, wrinkled, serrate, tomentose underneath; panicles axillary; heads ovate; stem four-cornered; flowers minute, white.—Found in America by Mutis.

5. *Lippia Cymosa*. Flowers cymed; leaves ovate, almost entire. This shrub has often several stems from the same root, each no larger than a goose-quill, round, and woody; the flowers come out at the top, they are small, and many together.—Native of Jamaica.

Liquidambar; a genus of the class Monœcia, order Polyandria.—GENERIC CHARACTER. *Male Flowers*: numerous, on a long conical loose ament. *Calix*: involucre common four-leaved; leaflets ovate, concave, caducous; the alternate ones shorter. *Corolla*: none. *Stamina*: filamenta numerous, very short, on a body convex on one side, flat on the other; antheræ upright, twin, four-furrowed, two-celled.—*Female Flowers*: at the base of the male spike, heaped into a globe. *Calix*: involucre as in the male, but double; perianths proper bell-shaped, cornered, several, connate, warty. *Corolla*: none. *Pistil*: germen oblong, growing to the perianth; styles two, awl-shaped; stigmas growing on one side, length of the style, recurved, pubescent. *Pericarp*: capsules as many, ovate, one-celled, bivalve, at the tip acute, disposed into a globe, woody. *Seeds*: several, oblong, glossy, with a membrane at the point, mixed with a great many chaffy corpuscles. Gærtner has furnished us with the following *Emendations*.—*Pistil*: germina two, conjoined between each other, and with the perianth; style to each long, awl-shaped; stigma recurved. *Pericarp*: capsules twin, leathery, beaked, one-celled, gaping inwards. *Seeds*: several, oblong, glossy, compressed, ending in a little membrane. **ESSENTIAL CHARACTER.** *Male*. *Calix*: common, four-leaved. *Corolla*: none. *Filamenta*: numerous. *Female*. *Calix*: in a globe, four-leaved. *Corolla*: none. *Styles*: two. *Capsules*: many in a globe, two-valved, many-seeded.—The species are,

1. *Liquidambar Styraciflua*; *Maple-leaved Liquidambar*, or *Sweet Gum*. Leaves palmate-lobed, with the sinuses of the base of the veins villose. The trunk of this tree is usually two feet in diameter, straight, and free from branches to the height of about fifteen feet; from which the branches spread and rise, in a conic form, to the height of forty feet and upwards from the ground. The leaves of this species are distinguished from those of the second, by the little tufts of hairs placed where the veins divide from the midrib. From between the wood and the bark issues a fragrant gum, which trickles from the wounded trees, and, by the heat of the sun, congeals into transparent drops, which the Indians chew as a preservative to their teeth. It is an excellent balsamic medicine, inferior to none, for the whites, and weaknesses occasioned by venereal disorders: it operates by urine, brings away gravel, and is beneficial in disorders of the lungs: it may be chewed in small quantities, like Gum Arabic, and smells so like Balsam of Tolu, that it is not easy to distinguish them. The bark of this tree is of singular use to the Indians, for covering their huts: the wood has a fine grain, and is beautifully variegated; but when wrought too green, is apt to shrink: to prevent which, no less than eight or ten years is sufficient to season the plants; after which, it forms excellent timber, and is used in wainscoting.—It is a native of clayey ground in North America. The seeds of this tree, if sown in the spring, commonly remain in the ground a whole year,

before the plants come up; so that the surest way to raise them, is to sow the seeds in boxes or pots of light earth; which may be placed in a shady situation during the first summer, and be removed in autumn to where they can have more sun: but if the winter should prove severe, it will be proper to cover them with pease-haulm, or other light covering; which ought constantly to be removed in mild weather. In the succeeding spring, if these boxes or pots be placed upon a moderate hot-bed, it will cause the seeds to come up early, so that the plants will have time to get strength before the winter; but during the two first winters, it will be proper to screen them from severe frost, as they will afterwards bear the cold very well.

2. *Liquidambar Imberbe*; *Oriental Liquidambar*. Leaves palmate-lobed, with the sinuses of the base of the veins smooth.—Native place unknown.

Liquorice. See *Glycyrrhiza*.

Liquorice Vetch. See *Astragalus*.

Liquorice, Wild. See *Abrus*.

Lirioconfancy. See *Convallaria Maialis*.

Liriodendron; a genus of the class Polyandria, order Polygynia.—GENERIC CHARACTER. *Calix*: involucre proper two-leaved; leaflets triangular, flat, deciduous; perianth three-leaved; leaflets oblong, concave, spreading, petal-form, deciduous. *Stamina*: filamenta numerous, shorter than the corolla, linear, inserted into the receptacle of the fructification; antheræ linear, growing longitudinally to the sides of the filamentum. *Pistil*: germina numerous, disposed into a cone; style none; stigma to each globose. *Pericarp*: none; seeds imbricated into a body resembling a strobile. *Seeds*: numerous, ending in a lanceolate scale, emitting an acute angle towards the base of the scale from the inner side, compressed at the base, acute. **ESSENTIAL CHARACTER.** *Calix*: three-leaved. *Petals*: six seeds imbricated into a strobile.—The species are,

1. *Liriodendron Tulipifera*; *Common Tulip Tree*. Leaves lobed. Mr. Marshall describes the tulip-tree as seventy or eighty feet in height. He mentions two varieties, one with yellow, and the other with white wood: the first soft and brittle, much used for boards, and heels of shoes, also for turning into bowls, trenchers, &c. the white heavy, tough, and hard, sawed into joist boards, &c. for buildings. He remarks that the flower has sometimes seven petals, or more. The young shoots of this tree are covered with a smooth purplish bark; they are garnished with large leaves, the footstalks of which are four inches long. The flowers are produced at the end of the branches; they are composed of six petals, three without, and three within, which form a sort of bell-shaped flower: whence the inhabitants of North America give it the title of Tulip. These petals are marked with green, yellow, and red spots, making a fine appearance when the trees are well charged with flowers. The time of this tree's flowering is in July; and when the flowers drop, the germen swells, and forms a kind of cone: but these do not ripen in England. Catesby, in his *Natural History of Carolina*, says, there are some of these trees in America, which are thirty feet in circumference, making several bends or elbows; which render the trees distinguishable at a great distance, even when they have no leaves on them. They are found in most parts of the northern continent of America, from the Cape of Florida to New England; where the timber is of great use, particularly for making of periaugas, their trunks being large enough to be hollowed into the shape of those boats; so they are of one piece. Kalm observes, that it is very agreeable at the end of May to see one of these large trees with its singular leaves, and covered for a fortnight toge-

ther with flowers, which have the shape, size, and partly the colour, of tulips; the wood is used for canoes; whence the Swedes in North America call it Canoe-tree. He speaks of having seen a barn of considerable size, the sides and roof of which were made of a single tulip-tree split into boards. But one inconvenience attends it, for there is no wood that contracts and expands itself so much as this. The bark is divisible into very thin laminæ, which are tough, like fibres of bass-mats: it is pounded, and given to horses that have the bots. The roots are supposed to be as efficacious in agues as Jesuit's bark.—One of the handsomest trees of this kind is in the garden of Mr. Jones, at Waltham Abbey.—This tree is propagated by seeds, which are annually imported in great plenty from America. They may either be sown in pots or tubs filled with light earth from the kitchen-garden, or in a bed in the full ground: those which are sown in the first way may be placed on a gentle hot-bed, which will forward their growth, so that the plants will acquire more strength before winter. When they are thus treated, the glasses of the hot-bed should be shaded from the sun every day, and the earth in the pots should be frequently refreshed with water; for unless it is kept moist, the seeds will not grow: but this must be done with care, so as not to make it too wet, which will rot the seeds. When the plants appear, they must be still shaded in the heat of the day from the sun; but fresh air must be admitted daily, to prevent their drawing up weak; and as the season advances, they must be gradually hardened, to bear the open air. While the plants are young, they do not require much sun, and should be either shaded, or placed where the morning sun only shines upon them; they must also be constantly supplied with water, but not have it in too great plenty. As the young plants commonly continue growing late in the summer, so when there happens early frosts in autumn, it often kills their tender tops, which occasions their dying down a considerable length in winter; therefore they should be carefully guarded against these first frosts, which are always more hurtful to them than harder frosts afterwards, when their shoots are better hardened: however, the first winter after the plants come up, it will be the better way to shelter them in a common hot-bed frame, or to arch them over with hoops, and cover them with mats; exposing them always to the open air in mild weather. The following spring, just before the plants begin to shoot, they should be transplanted into nursery-beds, in a sheltered situation, where they are not too much exposed to the sun. The soil of these beds should be a soft gentle loam, not too stiff, nor over light; this should be well wrought, and the clods well broken and made fine. Great care must be taken not to break the roots of the plants, in taking them up, for they are very tender; they should be planted again as soon as possible; for if their roots are long out of the ground, they will be much injured thereby.—These may be planted in rows at about a foot distance, and at six inches' distance in the rows: for as they should not long remain in these nursery-beds, so this will be room enough for them to grow; and by having them so close, they may be shaded in the summer, or sheltered in the winter with more ease than when they are farther apart. When the plants are thus planted, if the surface of the beds is covered with rotten tanner's bark, or with moss, it will prevent the earth from drying too fast; so that the plants will not require to be so often watered, as they must be where the ground is exposed to the sun and air: after this, the farther care will be to keep them clean from weeds; and if the latter part of summer should prove moist, it will occasion the plants to grow late in autumn; so the tops will be tender, and liable to be killed by the first frosts: in this case they should be covered with mats, to protect them. If

the plants make great progress the first summer, they may be transplanted again the following spring; part of them may be planted in the places where they are to remain, and the other should be planted in a nursery, where they may grow two or three years to acquire strength, before they are planted out for good: though the younger they are planted in the places where they are to stand, the larger they will grow, for the roots run out into length, and when they are cut, it greatly retards their growth: so that these trees should never be removed when large; for they rarely succeed, when they are grown to a large size, before they are transplanted. When the seeds are sown upon a bed in the full ground, the bed should be arched over with hoops, and shaded in the heat of the day from the sun, and frequently refreshed with water; as also should the plants when they appear: for when they are exposed much to the sun, they make small progress. The care of these in summer must be to keep them clean from weeds, supplying them duly with water, and shading them from the sun in hot weather: but as these seeds will not come up so soon as those which were placed on a hot-bed, they generally continue growing later in autumn, and will therefore be sheltered from the early frosts; for as their shoots will be much softer than those of the plants which had longer time to grow, so if the autumnal frosts should prove severe, they will be in danger of being killed down to the surface of the ground; by which the whole summer's growth will be lost, and the unprotected plants are sometimes entirely killed by the first winter. As these plants will not have advanced so much in their growth as the other, they should remain in the seed-bed, to have another year's growth, before they are removed; therefore all that will be necessary the second year, is to keep them clean from weeds. After the plants have grown two years in the seed-beds, they will be strong enough to remove; therefore in the spring, just at the time when their buds begin to swell, they should be carefully taken up, and transplanted into nursery beds, and treated in the same way as has been before directed for the plants raised upon a hot-bed. There are some persons who propagate this tree by layers, which are commonly two or three years before they take root; and the plants so raised seldom make such straight trees as those raised from seed, though indeed they will produce flowers sooner; as is always the case with stunted plants. This tree should be planted on a light loamy soil; on which, when not too dry, it will thrive much better than upon a strong clay, or a dry gravelly ground: for in America they are chiefly found upon a moist light soil, growing to a prodigious size. It will not however be proper to plant these trees in a soil which is too moist in England, which might rot the fibres of the roots, by the moisture continuing too long about them; especially if the bottom be clay, or a strong loam, which will detain the wet. To raise them in the open ground, at the beginning of March prepare a bed of good mellow rich earth well mixed with old rotten cow-dung, exposed to the sun, and sheltered from cold winds: place an old frame over the bed; and having sown the seeds, sift over them, half an inch thick, a soil composed some months before, of one load of old pasture earth, one of well rotted cow-dung, and half a load of sea or fine pit sand. Some of these seeds will probably make their appearance in nine or ten weeks, but much the greater part will lie in the ground till next spring. Water the beds therefore no more than barely sufficient to cherish the plants that have appeared: for four or five weeks screen them from the sun during the heat of the day, but afterwards let them receive its full influence. During bad weather in winter throw double mats over the frames. In March, the succeeding year, pick off all mossy hard-crust ed earth from the bed,

smooth it, and sift on some fine rich mould. At the end of April, or the beginning of May, plants will appear in abundance; when they must be frequently, but gently, watered. Till the beginning of August, they must be screened from a mid-day sun by part of an old reed-fence, or by nailing some thin boards together, high enough to shade the bed: after this, it will only be necessary to give them frequent moderate waterings, and to throw a mat over the frame during any severe winter storm. At the beginning of April, in the next season, take up the plants with a trowel, without bruising the roots; and if they cannot be planted immediately, mix a pailful of sifted mould and water to the consistence of pap; draw the plants through it, till as much adhere as will cover their roots and fibres: in this condition they may be kept several days out of the ground. Cut only a little of the tap-roots smoothly off, but let all the fibres remain; and then plant them in drills cut out with the spade, at a foot distance row from row, and six inches in the row: plant five of these lines, and then leave an alley three feet wide; water them frequently and plentifully during the summer months; throw mats over them, in case of very severe frost in the first winter, and let them remain two years. Then remove them to another nursery, in rows three feet and a half distant, and eighteen inches in the row, and let them continue three years; at the end of which, they will be of a good size for planting where they are to remain. No tree bears pruning its roots and branches worse than this; none however surpasses it in beauty and stateliness: so that it deserves a place in all noble and elegant plantations.

2. *Liriodendron Liliifera*. Leaves lanceolate. This is a middle-sized tree, with spreading branches; flowers pale, large, scentless, heaped at the ends of the branches, one on a peduncle.—Native of China near Canton, and of Amboyna.

Lisianthus; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted; leaflets lanceolate, keeled, membranaceous on the margin, very short, permanent. *Corolla*: one-petalled, funnel-form; tube long, somewhat ventricose, straitened at the base within the calix; border five-parted; divisions lanceolate, shorter than the tube, recurved. *Stamina*: filamenta five, filiform, longer than the tube; antheræ ovate, incumbent. *Pistil*: germen oblong, sharp-pointed; style filiform, length of the stamina, permanent; stigma headed, two-plated. *Pericarp*: capsule oblong, acuminate, two-celled; the margins of the valves intorted. *Seeds*: numerous. ESSENTIAL CHARACTER. *Calix*: keeled. *Corolla*: with a ventricose tube, and recurved divisions. *Stigma*: two-plated; capsule two-celled, two-valved; the margins of the valves intorted.

—The species are,

1. *Lisianthus Longifolius*. Leaves lanceolate; segments of the corolla lanceolate, acute. This elegant little plant rises generally to the height of fourteen or sixteen inches, or more: the flowers are large, and appear at the ends of the branches.—Native of Jamaica, in a dry, sandy, but cool soil. All the plants of this genus require to be kept in the bark-stove.

2. *Lisianthus Cordifolius*. Leaves cordate; segments of the corolla lanceolate, acute. This is said to be a variety of the preceding.—Native of Jamaica. See the preceding.

3. *Lisianthus Exsertus*. Leaves ovate-lanceolate, peduncles trichotomous; genitals very long.—Native of Jamaica. See the first species.

4. *Lisianthus Latifolius*. Leaves lanceolate-elliptic, acuminate; peduncles trichotomous; segments of the corolla erect, genitals included.—Native of Jamaica. See the first species.

5. *Lisianthus Umbellatus*. Leaves elongated, obovate; flowers terminating, peduncled, umbelled; segments of the

corolla very short, blunt, upright.—Native of Jamaica. See the first species.

6. *Lisianthus Frigidus*. Leaves ovate, acuminate, coriaceous; panicle terminating, trichotomous; corollas ventricose, with rounding segments.—Native of the mountains of Guadeloupe. See the first species.

7. *Lisianthus Sempervirens*. Leaves lanceolate-elliptic; segments of the corolla ovate, blunt. See *Bignonia Sempervirens*: it is the same plant.

8. *Lisianthus Glaber*. Smooth: leaves ovate, petioled; corymbs terminating; stem upright, branched, round, leafy; flowers on few-flowered simple umbels; corolla yellow.—Found by Mutis in South America. See the first species.

9. *Lisianthus Chelonoides*. Smooth: leaves opposite, subconnate, oblong; panicle terminating, dichotomous, racemose; stem herbaceous, simple, round, smooth, from two to three feet high; flowers alternate, remote, directed one way, pendulous, yellow. The herb is very bitter, and strongly purgative.—Native of Surinam. See the first species.

Lita; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, erect, coloured, five-cleft, sharp, permanent. *Corolla*: one-petalled, salver-shaped; tube cylindric, very long, enlarged at the base and tip; border five-cleft; divisions ovate, spreading. *Stamina*: filamenta none; antheræ five, twin, in the throat of the corolla. *Pistil*: germen oblong; style filiform, length of the tube; stigma headed, truncated. *Pericarp*: oblong, one-celled, two-valved. *Seeds*: numerous, sawdust-like, affixed to the margins of the valves. *Observe*. This genus is allied to *Gentiana*, but differs in the corolla, pistil, and fruit. ESSENTIAL CHARACTER. *Calix*: five-cleft, with two or three scales at the base. *Corolla*: salver-shaped, with a very long tube, dilated at the base and throat; border five-cleft; antheræ twin, inserted in the throat; capsule one-celled, two-valved. *Seeds*: numerous.—The species are,

1. *Lita Rosea*. Flowers in pairs; segments of the corolla acute; root tuberous, fibrous, about a foot deep in the ground; stem knobbed, quadrangular; corolla rose-coloured.—It grows wild in Guiana, where the root, which much resembles potatoes, is eaten by the inhabitants. It flowers in May.

2. *Lita Cœrulea*. Flowers in pairs; segments of the corolla rounded; colour of the corolla blue. It flowers in May.—Native of Guiana.

Lithophila; a genus of the class Diandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth three-leaved; leaflets lanceolate, sharp. *Corolla*: petals three, ovate-lanceolate, upright, converging, length of the leaflets of the calix; nectary two-leaved; leaflets opposite, smaller than the corolla, keeled, acute, upright, compressed. *Stamina*: filamenta two, awl-shaped, upright from the base of the germen, of the length of the nectary; antheræ roundish. *Pistil*: germen roundish, superior; style upright, length of the stamina; stigma obtuse, emarginate. *Pericarp*: two-celled. *Seed*: undivided. ESSENTIAL CHARACTER. *Calix*: three-leaved. *Corolla*: three-petalled. *Nectary*: two-leaved.—The only species known is,

1. *Lithophila Muscoides*.—Native of Navaza.

Lithospermum; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, oblong, straight, sharp, permanent; divisions awl-shaped, keeled. *Corolla*: one-petalled, funnel-form, length of the calix; tube cylindric; border half five-cleft, obtuse, upright; throat perforated, naked. *Stamina*: filamenta five, very short; antheræ oblong, incumbent, covered.

Pistil: germina four; style filiform, length of the stamina; stigma obtuse, emarginate. *Pericarp*: none; calix grown larger, upright, containing the seeds in its bosom; seeds four, rather oblong, obtuse, gibbous. **ESSENTIAL CHARACTER.** *Calix*: five-parted. *Corolla*: funnel-form, perforated at the throat, naked.—The species are,

1. *Lithospermum Officinale*; *Common or Officinal Gromwell, Gromill, or Graymill*. Seeds smooth and even; corollas scarcely longer than the calix; leaves lanceolate; root perennial, strong; stems erect, roundish. The seeds operate powerfully as a diuretic, and are said to be serviceable in the stone, gravel, and most other obstructions: the best method of giving them is in barley-water, after having reduced them to a fine powder.—Native of most parts of Europe, in dry, gravelly, and chalky soils. It flowers in May and June. All the plants of this genus may be cultivated, by sowing their seeds soon after they are ripe in a bed of fresh earth, allowing them room, and keeping them clear from weeds. They will thrive in almost any soil and situation; and where the seeds are permitted to scatter, generally rise without care. The sixth and seventh are handsome, and worth cultivating.

2. *Lithospermum Arvense*; *Corn or Bastard Gromwell*. Seeds ovate, wrinkled; calicine leaflets lanceolate; corollas scarcely longer than the calix; leaves lanceolate, sharpish, hispid; root annual, small, and not much branched: its bark abounding with a deep red dye, which stains paper and linen, and is easily communicated to oily substances; hence it is sometimes called Bastard Alkanet. Linneus, in his *Flora Suecica*, informs us, that the country girls in the north of Sweden use the root to stain their faces on days of festivity.—It is common in corn-fields, and waste places; flowering from May to July. See the first species.

3. *Lithospermum Incanum*; *Hoary Gromwell*. Seeds rough; spikes terminating, compound, contracted; leaves linear, villose.—This is a shrubby species, found in Teautea and Savage Islands. See the first species.

4. *Lithospermum Virginianum*; *Virginian Gromwell*. Corollas larger than the calix, acute, rough-haired on the outside; leaves ovate, acute, hispid, nerved; root perennial; corolla white.—Native of Virginia and Maryland. See the first species.

5. *Lithospermum Tinctorum*; *Dyer's Gromwell*. Seeds smooth and even; spike solitary, terminating, directed one way; bractes lanceolate; leaves linear-lanceolate, blunt; root fusiform, two inches long, annual; stems several.—Native of Egypt.

6. *Lithospermum Orientale*; *Yellow Gromwell, or Bugloss*. Flowering branches lateral; bractes cordate, embracing; stem barren, upright; perennial.—It flowers in May and June; and is a native of the Levant. See the first species.

7. *Lithospermum Purpureo-cæruleum*; *Creeping Gromwell*. Seeds smooth and even; corollas twice as long as the calix; leaves lanceolate, somewhat hairy; the long woody perennial root produces many round, hairy, leafy stems, most of which are procumbent, and throw out roots; corolla first purple, then blue, with a pale reddish tube.—Native of most of the temperate parts of Europe: found near Taunton, in Somersetshire, and near Denbigh, in North Wales; also in a chalky soil near Greenhithe, in Kent. See the first species.

8. *Lithospermum Tenuiflorum*. Corollas filiform; leaves linear-lanceolate, strigose; stem upright.—Native of Egypt. See the first species.

9. *Lithospermum Fruticosum*; *Shrubby Gromwell*. Shrubby: Leaves linear, hispid; stamina equalling the corolla; root perennial, running deep into the ground; stem upright,

shrubby, from two to three feet high, pretty closely set with hairs.—Native of the south of Europe, and the Levant. See the first species.

10. *Lithospermum Callosum*. Leaves lanceolate-linear, callous, warted, hispid; stem suffruticose, hispid.—Native place unknown. See the first species.

11. *Lithospermum Ciliatum*. Leaves ovate, hoary, callous at the edge, ciliate; stem suffruticose, muricated, hispid. It is a small, stiff, upright shrub, a span in height.—Native place unknown. See the first species.

12. *Lithospermum Dispermum*. Seeds only two; calices spreading; root annual; stem herbaceous, a hand high; corolla bluish white, small.—Native of Spain, between Madrid and Cadiz. See the first species.

13. *Lithospermum Latifolium*. Seeds turgidly ovate, Incid, cavo-punctate; leaves ovate-oblong, nervous; flowers pale yellow.—Found in shady woods from Virginia to Kentucky.

14. *Lithospermum Angustifolium*. Seeds the same as the preceding; flowers lateral, white; leaves linear, adpresso-pubescent; stem prostrate.—It grows in shady woods in the vicinity of the river Ohio.

15. *Lithospermum Apulum*. Seeds muricate; spikes terminal, fruitful; bractes lanceolate; leaves linear-lanceolate, acute; flowers yellow, very small.—It grows in the dry woods of Virginia, and in the neighbourhood of the rivers Ohio and Mississippi.

Littorella: a genus of the class Monœcia, order Tetrandria.—**GENERIC CHARACTER.** *Male*. *Calix*: perianth four-leaved, upright. *Corolla*: one-petalled; tube the length of the calix; border four-parted, upright, permanent. *Stamina*: filamenta four, filiform, very long, inserted into the receptacle; antheræ heart-shaped. *Female*, in the same plant. *Calix*: none. *Corolla*: one-petalled, conic, with slightly four-cleft mouth; permanent. *Pistil*: germen oblong; style filiform, very long; stigma acute. *Pericarp*: the investing corolla. *Seed*: nut one-celled. *Observe*. The flower is that of Plantain, but the fruit different. **ESSENTIAL CHARACTER.** *Male*. *Calix*: four-leaved. *Corolla*: four-cleft. *Stamina*: long. *Female*. *Calix*: none. *Corolla*: slightly four-cleft. *Styles*: long. *Seed*: a nut.—The only known species is,

1. *Littorella Lacustris*; *Plantain Shoreweed*. The roots shoot out long running fibres, which take root afresh, and thus in a short time cover the brink of the lakes with tufts of semi-cylindrical, linear, acute leaves, about two inches long.—Native of the north of Europe, on the shores of lakes. It has been observed on Hounslow Heath; near Lowestoff, in Suffolk; at Hoseley-lough, in Northumberland; is common in Scotland, and some parts of Wales, and on the margins of all the gravelly-shored lakes in Ireland.

Live-in-Idleness. See *Viola*.

Live-long. See *Telephium*.

Liver Wort. See *Lichen Caninus*.

Lizard's Tail. See *Saururus*.

Loasa: a genus of the class Polyandria, order Monogynia.—**GENERIC CHARACTER.** *Calix*: perianth five-leaved, superior, permanent; leaflets lanceolate, very spreading, with reflex sides. *Corolla*: petals five, obovate, hooded, large, extremely spreading; narrowed at the base into claws; nectary of five-leaflets, alternating with the petals, converging into an acute cone, rather shorter than the calix, lanceolate, rugose, awned with a double filamentum. *Stamina*: filamenta numerous, capillary, longer than the nectary, from fifteen to seventeen to each petal; antheræ incumbent, roundish. *Pistil*: germen subovate, seed-bearing; style filiform, upright, the length of the stamina; stigma simple, obtuse. *Pericarp*:

capsule top-shaped, one-celled, three-valved at the tip; valves semi-ovate, acute, spreading. *Seeds*: a great many, ovate, small; receptacles three longitudinal lines running from the bottom of the capsule to the incisures of the valves. *Observe*. In point of affinity it approaches *Mentzelia*; in habit and situation of the germen and seeds, it approaches the Cucurbitaceous plants. **ESSENTIAL CHARACTER.** *Calix*: five-leaved, superior. *Corolla*: five-petalled; petals hooded; nectary five-leaved, converging; capsule turbinate, one-celled, three-valved, many-seeded.—The only known species is,

1. *Loasa Hispida*. This is an elegant annual plant, rising from a fibrous white root, the thickness of the little finger; stems round, whitish-green, marked here and there with short brown longitudinal lines; flowers handsome, but scentless; petals yellow.—Native of South America.

Lobelia; a genus of the class Syngenesia, order Monogamia.—**GENERIC CHARACTER.** *Calix*: perianth one-leaved, five-cleft, very small, growing round the germen, withering; toothlets nearly equal, the two superior ones looking more upward. *Corolla*: one-petalled, irregular; tube cylindric, longer than the calix, divided longitudinally above; border five-parted; divisions lanceolate, of which the two superior ones are smaller, less reflex, more deeply divided, constituting an upper lip, the three inferior ones more spreading, frequently larger. *Stamina*: filamenta five, awl-shaped, the length of the tube of the petal, connate above; antheræ connate into an oblong cylinder, gaping five ways at the base. *Pistil*: germen sharp-pointed, inferior; style cylindric, length of the stamina; stigma obtuse, hispid. *Pericarp*: capsule ovate, two or three celled, two or three valved, gaping at the top, girt by the calix; dissepiments contrary to the valves. *Seeds*: a great many, very small; receptacle conic. **ESSENTIAL CHARACTER.** *Calix*: five-cleft. *Corolla*: one petalled, irregular. *Capsule*: inferior, two or three-celled.—The species are,

* *With entire Leaves.*

1. *Lobelia Simplex*; *Slender Lobelia*. Stem upright; leaves linear, quite entire; peduncles solitary. It is a small annual plant, scarcely a hand high.—Native of the Cape of Good Hope. See the thirty-eighth species.

2. *Lobelia Columnæ*; *Mealy Lobelia*. Leaves oblong, blunt, revolute, very much wrinkled, shining above, tomentose beneath; branch or stem somewhat woody, angular, tomentose, mealy.—Native of New Granada.

3. *Lobelia Bellidifolia*; *Daisy-leaved Lobelia*. Stem upright, panicled; leaves obovate, crenate.—Native of the Cape of Good Hope. See the thirty-eighth species.

4. *Lobelia Pinifolia*; *Pine-leaved Lobelia*. Shrubby; leaves linear, clustered, quite entire; flowers many, small, blue; they are found at the tops of the twigs, among the leaves.—Native of the Cape of Good Hope. See the thirty-eighth species.

5. *Lobelia Dortmanna*; *Water Lobelia*, or *Gladiole*. Leaves linear, two-celled, quite entire; stem almost naked, erect, round, hollow, smooth; flowers about nine, in a loose spike, above the water; corolla white, faintly tinged with blue. Linneus remarks, that the whole plant, even the leaves beneath the water, are milky, and that the flowering-stalk is of a length proportional to the depth of water in which the plant grows. It flowers in July and August.—Native of the north of Europe, in mountain lakes: hence it is found in Wales, Westmoreland, Cumberland, and Scotland. See the twenty-fourth species.

6. *Lobelia Tupa*. Leaves lanceolate, quite entire; raceme spiked. The root and herb of this species are a violent poison.—Native of Peru.

7. *Lobelia Kalmii*. Stem upright; leaves lanceolate-linear, bluntish, alternate, quite entire; raceme terminating, a foot high; corolla blue.—Annual, and a native of Canada. See the twenty-fourth species.

8. *Lobelia Paniculata*; *Panicled Lobelia*. Leaves linear, quite entire, panicled, dichotomous.—Native of the Cape of Good Hope. See the thirty-eighth species.

9. *Lobelia Grandis*; *Great Lobelia*. Leaves oblong, quite entire, smooth; corymbs bracted; corollas hispid.—Native of South America.

10. *Lobelia Ferruginea*; *Rust-coloured Lobelia*. Stem villose; leaves lanceolate, serrate, acute, where the veins anastomose rust-coloured-tomentose on both sides; genitals elongated.—Native of America.

11. *Lobelia Chinensis*; *Chinese Lobelia*. Leaves lanceolate, quite entire; flowers solitary, terminating; stem creeping; corolla pale blue.—Native of China, near Canton.

12. *Lobelia Cornuta*; *Horned Lobelia*. Leaves ovate, petioled; stamina very long. It is distinguished by its horned form, and the great length of the stamina.—Native of Cayenne.

13. *Lobelia Fulgens*. Plant erect, simple, subpubescent; leaves elongate-lanceolate, attenuate, very entire; raceme multiflorous.—It grows on the banks of the Mississippi. This species exceeds in splendour of colour, and size, the *Lobelia Cardinalis*.

** *With an upright Stem, and gashed Leaves.*

14. *Lobelia Phyteuma*. Leaves ovate-oblong, crenate; stem almost naked, spiked; antheræ hirsute, distinct.—Native of the Cape of Good Hope. See the thirty-eighth species.

15. *Lobelia Bulbosa*; *Tuberous-rooted Lobelia*. Stem upright; lower leaves pedate.—Native of the Cape of Good Hope. See the thirty-eighth species.

16. *Lobelia Triquetra*; *Tooth-leaved Lobelia*. Stem upright; leaves lanceolate, toothed; raceme terminating, leafless. It flowers from May to September.—Native of the Cape of Good Hope. See the thirty-eighth species.

17. *Lobelia Longiflora*; *Long-flowered Lobelia*. Leaves lanceolate, toothed; peduncles very short, lateral; tube of the corolla filiform, very long. This is an annual herbaceous elegant plant, seldom above fourteen or sixteen inches high; stem upright; corolla handsome, white. It is altogether very poisonous, and brings on an invincible purging. If, after handling it, the hand be unawares applied to the eyes or lips, it brings on an inflammation. Horses are said to burst with eating it: whence in the Spanish West Indies it is called *Reventa Cavallos*. It is well known in Dominica under the name of *Quedec*. It is also a native of Jamaica, Cuba, and Martinico, by rivulets, and in moist cool shady places. It flowers from June to August.—The seeds of this plant should be sown, after it is ripe, in pots filled with rich earth, and plunged into the tan-bed in the stove, observing to refresh the earth frequently with water. In the spring, these pots may be removed, and plunged into a hot-bed, which will soon bring up the plants: when they are fit to remove, they should be each transplanted into a separate small pot filled with rich earth, and plunged into a fresh hot-bed, shading them from the sun till they have taken new root; then they may be treated in the same way as other tender plants from the same country, in allowing them a large share of air in warm weather, and frequently refreshing them with water. In autumn the plants must be plunged into the tan-bed of the stove, where they will flower the following summer, and produce ripe seeds; soon after which the plants will decay. If the seeds of this plant are brought from the West Indies, they should be sown, as soon as they arrive, in pots filled with rich earth: and if it happen in the winter, the pots should be

plunged into the tan-bed in the stove; but if it be in the spring or summer, they may be plunged into a hot-bed in the common frames. These seeds, when sown in the spring, seldom grow the same year; therefore, the following autumn, the pots should be removed into the stove, and managed according to the above directions.

18. *Lobelia Tomentosa*; *Downy Lobelia*. Straight, tomentose; leaves linear, toothed; peduncles terminating, very long, one or two flowered.—Native of the Cape of Good Hope. See the thirty-eighth species.

19. *Lobelia Secunda*. Upright, smooth; lower leaves oblong, toothed; upper lanceolate, entire; peduncles racemed, directed one way.—Native of the Cape of Good Hope. See the twenty-fifth species.

20. *Lobelia Assurgens*; *Tree Lobelia*. Leaves broad-lanceolate, serrate, toothletted, and decurrent below; racemes compound, terminating; root perennial; stem herbaceous, three or four feet high; flowers numerous, heaped, blood-red, very large.—Native of the cooler mountains of Jamaica. For its propagation and culture, see the sixteenth species.

21. *Lobelia Patula*; *Spreading Lobelia*. Herbaceous, diffused, virgate, smooth; leaves ovate-toothed; peduncles lateral.—Native of the Cape of Good Hope. See the thirty-fourth species.

22. *Lobelia Acuminata*; *Pointed-leaved Lobelia*. Stem upright, suffruticose; leaves lanceolate, attenuated, serrulate; raceme terminating, many-flowered; flowers yellow.—Native of the lower shady hills of Jamaica. For its propagation and culture, see the seventeenth species.

23. *Lobelia Stricta*. Stem suffruticose; lower leaves ovate-lanceolate, smooth, toothletted, and prickly at the edge; raceme terminating, spiked.—Native of the island of Guadeloupe. See the seventeenth species.

24. *Lobelia Cardinalis*; *Scarlet Lobelia*, or *Cardinal's Flower*. Stem upright, herbaceous; leaves oblong-lanceolate, serrate, somewhat villose; flowers in a sort of spike; calices smooth; segments quite entire. The stalk is terminated by a spike or raceme of flowers of an exceedingly beautiful scarlet colour. They appear at the end of July and in August, when they make a fine appearance for a month or more; and, when the autumn proves favourable, they will produce good seeds here. It grows naturally by the side of rivers and ditches in North America.—Both this and the next are propagated by seeds, which, when they ripen in England, should be sown in autumn in pots filled with rich kitchen-garden earth, and placed under a common hot-bed frame; or, if the seeds come from their native countries, sow them as soon as they arrive, for if kept out of the ground till spring, they will lie a year in the earth before they will vegetate. The pots in which these seeds are sown should be exposed to the open air at all times in mild weather, and screened from hard rain and frost. In the spring, the plants will appear. They must have fresh air in mild weather, and be refreshed with water in dry seasons. As soon as they are fit to remove, let each be planted in a small pot, filled with the same rich earth, and placed in the shade till they have taken new root; then they may be set so as to enjoy the morning sun till autumn. Water them during the dry weather in summer, and when their roots have filled the small pots, remove them into larger. In autumn, put them under a common frame to screen them from winter frost, taking care that they have fresh air in fine weather. Next spring, new pot them, placing them in the morning sun, and taking care to water them in dry weather, which will cause their stalks to be stronger and produce larger spikes of flowers in August. There are many who propagate them by cutting their stalks into proper lengths, which they plant in pots filled with good

earth, or into an east border, covering them close with glasses. They frequently take root, but are not so good as seedlings.

25. *Lobelia Siphilitica*; *Blue Lobelia*, or *Cardinal Flower*. Stem upright; leaves ovate-lanceolate, subserrate; sinuses of the calix reflex; root perennial; stem from a foot to two feet in height; flowers axillary, solitary, numerous, large; corolla blue, varying in shades from a rich violet to a pale blue. It flowers from August to October, and is a native of Virginia.—Every part of the plant abounds with a milky juice, and has a rank smell. The root, which is the part prescribed for medical use, resembles tobacco in taste, and tends to excite vomiting. It derives its trivial name from its efficacy in the cure of syphilis, as experienced by the North American Indians, with whom it was a secret. Sir William Johnson purchased the secret; which has been published, and is as follows: A decoction is made of a handful of the roots in three measures of water. Of this, half a measure is taken in the morning fasting, and repeated in the evening: the dose is gradually increased till the purgative effects become too violent, when it is to be omitted for a day or two, and then renewed, till a perfect cure is effected. During the use of this medicine, a proper regimen is enjoined; and the ulcers also are to be frequently washed with the decoction, or, if deep and foul, to be sprinkled with the powder of the inner bark of the New Jersey Tea Tree, (see *Ceanothus Americanus*.) But although this plant is said to cure the disease in a very short time, its virtues have not been confirmed by any instances of European practice. For its propagation and culture, see the preceding species.

26. *Lobelia Lactescens*. Shrubby; leaves smooth, elliptic-lanceolate, serrate; peduncles axillary, solitary, without bractes; calices smooth.—Native of St. Helena.

27. *Lobelia Surinamensis*. Suffruticose; leaves oblong, serrate, smooth; peduncles axillary, solitary, bracted at the base; calices torulose. It flowers in April.—Native of the West Indies. See the seventeenth species.

28. *Lobelia Inflata*; *Bladder-podded Lobelia*. Stem upright; leaves ovate, subserrate, longer than the peduncle; capsules inflated; flowers small; corolla light blue.—Native of Virginia and Canada. Sow the seeds in autumn, in pots filled with rich earth, and treat the plants in the same way as above directed under the twenty-fourth species.

29. *Lobelia Cliffortiana*; *Purple Lobelia*. Stem upright; leaves cordate, even, obsoletely toothed, petioled; corymb terminating; flowers small, purplish.—Native of America. When the seeds are permitted to scatter on pots which stand near them, and these are sheltered from frosts, the plants will come up plentifully in the following spring; or if they be sown in pots in autumn, and sheltered in winter, the plants will rise in the following spring; and should be transplanted into small pots, placed under a frame.

30. *Lobelia Urens*; *Stinging Lobelia*. Stem upright, smooth, angular; leaves lanceolate, toothed, smooth; racemes spike-shaped; calicine segments awl-shaped, even; corolla bright blue. The whole plant is milky, of a warm taste, and the root, especially if chewed, excites a pungent sense of burning in the tongue.—Native of France, Spain, and England: it has been found on Shute Common, between Axminster and Honiton, flowering in July and August. Sow the seeds in autumn, on a warm border, or in pots filled with loamy earth, and placed under a common frame in winter. When they come up in the spring, transplant them into a border of soft loamy earth, or into other pots, shading them till they have taken new root, and duly watering them in dry weather, which will cause them to flower strong, and produce good seeds annually.

31. *Lobelia Minuta*; *Least Lobelia*. Root-leaves ovate; scapes axillary.—Native of the Cape of Good Hope. See the thirty-eighth species.

32. *Lobelia Volubilis*; *Twining Lobelia*. Stem twining.—Native of the Cape of Good Hope. See the thirty-eighth species.

33. *Lobelia Amoena*. Plant erect, very smooth; leaves lato-lanceolate, serrate; spikes multiflorous; laciniae of the calix very entire; flowers of a beautiful sky-blue. This grows to the height of from two to three feet, and is found on the mountains of Virginia and Carolina.

34. *Lobelia Glandulosa*. Plant erect; subracemose, subpubescent, lucid; leaves lanceolate, glandulous-serrate, subcarnous; flowers racemose, on short footstalks; laciniae of the calix revolute, dentated; flowers dark blue.—It grows from eight inches to a foot high, and is found in Pine-swamps from Virginia to Florida.

35. *Lobelia Puberula*. Plant erect, very simple, pubescent; leaves oblong-oval, repand-serrulate; flowers spicately, alternate, subsessile; germen hispid; calix ciliate; flowers middle size, sky-blue.—It grows from one to two feet high, and is found in the range of mountains from Virginia to Carolina.

*** *With a prostrate Stem, and gashed Leaves.*

36. *Lobelia Laurentia*; *Italian Annual Lobelia*. Stem prostrate; leaves lanceolate-oval, crenate; stem branched; peduncles solitary, one-flowered, very long.—Native of Italy about Pisa; also of the islands of Elba, Corsica, and Sicily.

37. *Lobelia Repanda*. Stem prostrate, quite simple; leaves roundish, repand-toothed; peduncles axillary, solitary, one-flowered.—Native of New Zealand.

38. *Lobelia Erinus*; *Small Spreading Lobelia*. Stem patulous; leaves lanceolate, somewhat toothed; peduncles very long; flowers small and blue, appearing in July.—Native of the Cape of Good Hope. If the seeds of this and of the next species, together with the seeds of all those which are natives of the Cape of Good Hope, be sown in autumn, they will succeed much better than when they are sown in spring. They may be sown in pots, and placed under a common hot-bed frame in winter, always exposing them to the open air in mild weather, but screening them from the frost. In the spring, they should be plunged into a moderate hot-bed, which will soon bring up the plants; and when they are fit to remove, they should be each planted in a separate small pot, filled with rich earth, and replunged into a moderate hot-bed. Here they should be shaded from the sun till they have taken new root, and afterwards must have a large share of air in mild weather. Then they should be gradually hardened to bear the open air, into which they ought to be removed in June, placing them in a sheltered situation, where they will flower in July; and if the season should prove favourable, the seeds will ripen in September; but if the season should prove cold, it will be proper to remove one or two plants into a glass-case, to obtain good seeds.

39. *Lobelia Erinoides*; *Trailing Lobelia*. Stems prostrate, filiform; leaves petioled, oblong, toothed.—Native of the Cape of Good Hope. See the preceding species.

40. *Lobelia Anceps*. Leaves lanceolate, decurrent; root annual.—Native of the East Indies.

41. *Lobelia Pubescens*; *Downy-leaved Lobelia*. Stems angular, prostrate; leaves lanceolate, toothed, rough-haired; peduncles axillary, one-flowered. It flowers from May to August.—Native of the Cape of Good Hope. See the thirty-eighth species.

42. *Lobelia Zeylanica*. Stems procumbent; leaves ovate, serrate, acute, lower obtuse; peduncles one-flowered; cap-

sules subvillose; flowers blue.—Native of China, in watery and shady places.

43. *Lobelia Lutea*; *Yellow Lobelia*. Stems procumbent; leaves lanceolate, serrate; flowers sessile, subspliked. It flowers in June and July.—Native of the Cape of Good Hope. See the thirty-eighth species.

44. *Lobelia Hirsuta*. Shrubby, hirsute, prostrate; leaves ovate, toothed; peduncles lateral, very long, two or three-flowered.—Native of the Cape of Good Hope. See the thirty-eighth species.

45. *Lobelia Coronopifolia*. Leaves lanceolate, toothed; peduncles very long.—Native of the Cape of Good Hope. See the thirty-eighth species.

**** *With a prostrate Stem, and entire Leaves.*

46. *Lobelia Depressa*. Depressed; leaves lanceolate; stem fleshy; flowers dark purple.—Native of the Cape of Good Hope. See the thirty-eighth species.

Loblolly Bay. See *Gordonia*.

Locker-Goulans. See *Trolius*.

Locust Tree. See *Hymenaea*.

Loeflingia; a genus of the class Triandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-leaved, upright; leaflets lanceolate, marked on each side at the base with a toothlet, sharp-pointed, permanent. *Corolla*: petals five, very small, oblong-ovate, converging into a globe, round. *Stamina*: filamenta three, length of the corolla; antherae roundish, twin. *Germen*: superior, ovate, three-cornered; style filiform, rather wider above; stigma a little obtuse. *Pericarp*: capsule ovate, somewhat three-cornered, one-celled, three-valved. *Seeds*: a great many, ovate, oblong. ESSENTIAL CHARACTER. *Calix*: five-leaved. *Corolla*: five-petalled, very small. *Capsule*: one-celled, three-valved.—The only known species is,

1. *Loeflingia Hispanica*. Root annual; branches prostrate, alternate; corolla white. It flowers in June.—Native of Spain, on open hills.

Loeselia; a genus of the class Didynamia, order Angiospermia.—GENERIC CHARACTER. *Calix*: perianth one-leaved, tubular, four-cleft, sharp, short, permanent. *Corolla*: one-petalled, unequal; tube the length of the calix; border five-parted; all the divisions deflected to the lower side, ovate-lanceolate, equal. *Stamina*: filamenta four, length of the corolla, of which two are shorter; all opposite the divisions of the petals, and reflected in a contrary situation to the corolla; antherae simple. *Pistil*: germen ovate; style simple, situated as the stamina; stigma thickish. *Pericarp*: capsule ovate, three-celled. *Seeds*: solitary or two, obscurely cornered. *Observe*. Gærtner remarks, that the stamina are five, one of which is shorter than the rest, and fastened to the nearest segment of the corolla, the rest inserted into the tube. ESSENTIAL CHARACTER. *Calix*: four-cleft; according to Gærtner, five-toothed. *Corolla*: with all the segments directed one way; Gærtner says, deeply five-cleft, with oblong ciliated segments. *Stamina*: opposite to the petal; according to Gærtner, five, unequal. *Capsule*: three-celled; gaping at top, according to Gærtner.—The only known species is,

1. *Loeselia Ciliata*. Stem upright; leaves opposite.—Found at La Vera Cruz in South America.

Logwood. See *Hamatoxyllum*.

Lolium; a genus of the class Triandria, order Digynia.—GENERIC CHARACTER. *Calix*: receptacle common, elongated into a spike, pressing the flowers, distichally spiked to the angle of the culm; glume univalve, opposite the shaft, awl-shaped, permanent. *Corolla*: bivalve; valvule inferior narrow-lanceolate, convolute, sharp-pointed, the length of

the calix; valve superior, shorter, linear, more obtuse, concave upwards; nectary two-leaved; leaflets ovate, obtuse, gibbous at the base. *Stamina*: filamenta three, capillary, shorter than the corolla; antherae oblong. *Pistil*: germen top-shaped; styles two, capillary, reflex; stigmas plumose. *Pericarp*: none. Corolla cherishes the seed, gapes, lets it fall. *Seed*: single, oblong, convex on one side, furrowed, flat on the other, compressed. *Observe*. The sessile spikes are placed in the same plane with the culm; hence the stem bears the office of a second calicine valve, deficient and opposite.—The species are,

1. *Lolium Perenne*; *Perennial Darnel*, or *Ray Grass*. Spikes awnless; spikelets compressed, longer than the calix, and composed of several flowers; root perennial, creeping; stems several from the same root. They are frequently russet-coloured at the joints. The spike is generally flat, but sometimes nearly cylindrical. The number of flowers in each spikelet varies from three or four, to six, seven, or eight, and even sometimes nine, ten, and eleven; but six or seven is the most common number.—This species was probably selected for cultivation because it is common, and the seeds are easily collected. In reply to the objections brought against this grass, Mr. Curtis judiciously remarks, that although it may not possess all that is desirable in a grass, it ought not therefore to be indiscriminately rejected. The complaint so generally urged against it, of its producing little more than stalks or bents, will be only found valid when the plant grows in upland pasture: in rich moist meadows its foliage is more abundant, and it seems to be the general opinion of Agriculturists, that it is highly nutritious and acceptable to cattle. Certainly it is not adapted to all soils and situations equally. Several sorts may even be preferable to it; and though early, it is not the first that springs; not only the Vernal, but the Fox-tail and Meadow Grasses, all excellent in their kind, appearing earlier than this. Ray Grass is, notwithstanding, valuable both as an early seed, and as being fit to mow for hay a fortnight before mixt grasses. For the latter use, the abundance of stalks is an excellence, provided the grass be cut whilst the sap is in them, the chief nutriment of hay residing in these. This grass is usually sown with clover, upon such lands as are designed to be ploughed again in a few years, and the common method is to sow it with Spring Corn; but from many repeated trials, it has always been found, that by sowing their seeds in August, when a few showers have fallen, the crop has answered much better than any sown in the common way; for the grass has often been so rank, as to afford a good feed the same autumn; and in the following spring there has been a ton and half of hay per acre mowed very early in the season, and this has been upon cold sour land: this proves it to be the best season for sowing these grasses, though it will be very difficult to persuade those persons to adopt this practice who have been long wedded to old customs. The necessary quantity of seed is about two bushels, and eight pounds of the common clover, to an acre. This will produce as good plants as can be desired; but is not to be practised upon lands where the beauty of the verdure is principally regarded, but only where profit is the main end in view. When this grass is fed, mow off the bents in the beginning of June, otherwise they will dry upon the ground, and have the appearance of a stubble field all the latter part of summer; and they will not only be disagreeable to the sight, but troublesome to the cattle, who will not touch them. By permitting them to stand, the after growth of the grass is greatly retarded, and the beautiful verdure lost for three or four months; so that it is good husbandry to mow the bents before they grow too dry, and

rake them off the ground: if they are then made into hay, it will serve for cart-horses or dry cows in the winter. This plant is common in most parts of Europe, by way-sides, and in pastures, flowering in June. It is called *Ray Grass* from *Iraie*, the name given to the third species by the French, who call this *Fausse Iraie*. Ray calls it, *Red Darnel Grass*; it is sometimes called *Crap*; in Devonshire, *Eaver*; in Norfolk, *White Nonesuch*. The Germans give it many names, *Perennirende*, or *Dauernde Lolch*, *Winter Lolch*, *Susser Lolch*, *Englische Reygrass*, &c.; the Danes call it, *Raigræs*; the Swedes, *Renrepe*, *Engelmans Rijegras*; the Italians, *Loglio Vivace*, *Loglio Salvatico*, *Fenice*; the Spaniards, *Ballico*, *Vallico*; the Portuguese, *Joyo Vivace*; and the Russians, *Pschanez*.

2. *Lolium Tenue*. Spike awnless, round; spikelets three-flowered. This is smaller than the preceding, and is distinguished by the tenuity of the culm and spike.—Native of France and Germany.

3. *Lolium Temulentum*; *Annual Darnel*, or *Ray Grass*. Spike awned; spikelets compressed, many-flowered; root annual; stems or culms from two to three feet high, upright. There is a variety without awns, and with a smooth culm, which withering makes a distinct species, under the name of *White Darnel*. Though there can be no doubt that the Perennial and Annual Darnel are distinct species, yet we are at a loss for specific distinctions; for the first has sometimes awns to the flowers, and the latter very often none. It is, however, besides being annual, taller and larger in every respect, and of a paler hue. Its place of growth is also different; for it is a weed among corn, especially wheat and barley; and also among flax: flowering in July and August. The flour of the seeds, mixed with wheat-flour, disorders the human body, producing vomiting, purging, and violent colics; but it has not a sensible effect unless taken in considerable quantity; or, as Linneus says, unless it be eaten hot. The seed, malted with barley, soon occasion drunkenness: hence the French name *Iraie*; and, by corruption, our English *Ray*. In Yorkshire, it is called *Droke*; and in Ireland, *Sturdy*. The Germans call it *Jakrige Lolch*, and *Germaine Lolch*, with about thirty other names; the Danes, *Heyre* and *Heyregræs*, &c. the Swedes, *Darrepe*; the Italians, *Loglio*, *Gioglio*, and *Zizania*; the Spaniards, *Joyo*, *Cizana*, and *Zizana*; the Portuguese, *Joyo*, *Zizania Bastarda*, and the Russians, *Kukol*. In this enlightened age, it can scarcely be necessary to correct an old vulgar error, that wheat degenerates into this grass. The fact is, that in very wet seasons, and among very bad husbandmen, the Darnel has so far prevailed, as to suffocate the wheat, and to take its place. Celsus recommends the meal of *Lolium* to be used in poultices, in common with that of wheat, for barley and lentil. Those who do not keep their wheat free from this Darnel, which is sown along with the seed of wheat, and may be separated from it by the sieve, are guilty of unpardonable negligence; as it is very injurious, and may be easily extirpated.

4. *Lolium Bromoides*; *Sea Darnel*. Panicle simple, pointing one way; spikelets awned; root annual; culms several, from six inches to a foot high. It flowers in June and July.—Native of England, in loose sand on the sea coast.

5. *Lolium Distachyon*. Spikes in pairs; calices one-flowered; corollas woolly; culms decumbent, branched at the base.—Native of Malabar.

Lonchitis; a genus of the class Cryptogamia, order Filices.—GENERIC CHARACTER. *Capsules*: disposed in lunulated lines, lying under the sinuses of the frond.—These Ferns, being natives of very hot climates, must be planted in pots, and plunged into the bark-pit: they may be increased by parting

the roots. In summer they should have plenty of free air, and be frequently watered.—The species are,

1. *Lonchitis Hirsuta*. Fronds pinnatifid, blunt, quite entire; shoots branched, hirsute, four feet high.—Native of South America and Jamaica.

2. *Lonchitis Aurita*. Fronds pinnate, the lowest pinnae two-parted; shoots undivided, prickly.—Native of South America.

3. *Lonchitis Repens*. Fronds pinnate; pinnae alternate, sinuate; shoots branched, prickly.—Native of South America.

4. *Lonchitis Pedata*. Frond pedate; pinnae pinnatifid, serrulate.—Native of Jamaica, in the mountains of New Liguance.

5. *Lonchitis Tenuifolia*. Arborescent: fronds decom-pounded; leaves pinnate; pinnae linear-oblong, serrate, the lower pinnatifid.—Native of the Isle of Tanna, in the South Seas.

London Pride. See *Saxifraga*.

Lonicera; a genus of the class Pentandria, order Monogynia.—GENERIC CHARACTER. *Calix*: perianth five-parted, superior, small. *Corolla*: one-petalled, tubular; tube oblong, gibbous; border five-parted; divisions revolute, one of which is more deeply separated. *Stamina*: filamenta awl-shaped, nearly the length of the corolla; antheræ oblong. *Pistil*: germen roundish, inferior; style filiform, the length of the corolla; stigma obtuse-headed. *Pericarp*: berry umbilicated, two-celled. *Seeds*: roundish, compressed. *Observe*. The first species has the inferior division of the corolla separated twice as deep; berries distinct: the sixth has the divisions of the corolla cut almost equally deep; berries distinct: the eighth has the lower division of the corolla twice as deeply cut; two berries seated on the same base: the tenth has the divisions of the corolla almost equally cut; two berries on the same base: the twelfth and fourteenth are singular, in having one germen for two floscules, like *Mitchella*: the sixteenth has the corolla nearly bell-shaped; fruit two-celled, half four-celled; seeds solitary. ESSENTIAL CHARACTER. *Corolla*: one-petalled, irregular. *Berry*: many-seeded, two-celled, inferior: according to Gærtner, in the tenth, one-celled, and in the twelfth, three-celled.—The species are,

* *Periclymena*, with a twining Stem.

1. *Lonicera Caprifolium*; *Italian Honeysuckle*. Flowers ringent, in terminating whorls; leaves deciduous, the upper ones connate-perfoliate. This is a very smooth shrub, in its natural state twining round trees, with its long, round, opposite branches; flowers about six in a whorl, slender and delicate, white, reddish-white, red, or yellow, extremely fragrant. There are three varieties.—Native of the south of Europe. The Germans call it *Geisblatt*; the Dutch, *Italiansche Kamperfolie*; the Danes, *Italiaensk Gedeblad*; the Swedes, *Italienst Getblad*; the French, *Chevrefeuille des Jardins*, or *D'Italie*; the Italians, *Madreselva*, *Caprifoglio*; the Spaniards, *Madreselva*; the Portuguese, *Matrisylva*. A strong decoction of Honeysuckle-leaves is no despicable remedy in complaints arising from obstructions of the liver. It operates by urine, and is a good ingredient in gargles for sore throats. The distilled water of the flowers is much esteemed by many as an excellent cosmetic. All the sorts of Honeysuckle are propagated either by layers or cuttings: when by layers, the young plants only should be chosen. They should be layed in the autumn, and by the following autumn will have taken root; when they should be cut off from the plants, and either planted where they are to remain, or into a nursery, to be trained up for standards, which must be done by fixing down stakes to the stem of each plant, to which their principal stalk should be fastened, and all the others cut off; the

principal stalk must be trained to the intended height of the stem, and should then be shortened, to force out lateral branches, which should be stopped, to prevent their growing too long; by constantly repeating this, as the shoots are produced, they may be formed into a sort of standard: but if any regard be had to their flowering, they cannot be formed into regular heads; for by constantly shortening their branches, the flower-buds will be cut off, so that few flowers can be expected: and as it is an unnatural form for these trees, but few of them should be so sacrificed; for when they are planted near other bushes, among the branches of which the shoots of the honeysuckles may run and mix, they will flower much better, and have a finer appearance than where more regularly trained. When the plants are in the nursery, if two or three of the principal shoots are trained up to the stakes, and the others are entirely cut off, they will be fit to transplant in the following autumn to the places where they are to remain; for though the roots may be transplanted of a greater age, yet they do not thrive so well as when they are removed while they are young. When these plants are propagated by cuttings, they should be planted in September, as soon as the ground is moistened by rain. Three of the four joints of the cuttings should be buried in the ground; from the fourth, remaining above the surface, the shoots will be produced. They may be planted in rows, at about a foot distance row from row, and four inches asunder in the rows, treading the earth close to them; and as the Evergreen and late Red Honeysuckles are a little more tender than the other sorts, if the ground between the rows where these are planted is covered with tanner's bark, or other mulch, to keep out the frost in winter, and the drying winds of the spring, it will be of great advantage to the cuttings: and if the cuttings have a small piece of the two years' wood at their bottom, there will be no hazard of their taking root. The plants which are raised from cuttings are preferable to those which are propagated by layers, as they have generally better roots. They may also be propagated by seeds; but unless they are sown in the autumn, soon after they are ripe, the plants will not come up the first year. They will grow in any soil or situation. Few shrubs deserve to be cultivated before those of this genus; for their flowers are very beautiful, and perfume the air to a great distance with their odour, especially in the mornings and evenings, and in cloudy weather, when the sun does not evaporate their odour, and raise it too high to be perceptible: so that in all retired walks there cannot be too many of them intermixed with other shrubs.

2. *Lonicera Dioica*; *Glaucous Honeysuckle*. Whorls sub-capitate, bracted; leaves deciduous, glaucous beneath, the upper ones connate-perfoliate; corollas ringent, gibbous at the base.—Native of North America.

3. *Lonicera Sempervirens*; *Trumpet Honeysuckle*. Spikes naked, terminating; the upper leaves connate-perfoliate; corollas almost regular; tube bellying at top. There are two varieties, if not distinct species, of this; one much hardier than the other. It has been long known in our gardens by the name of Virginia Trumpet Honeysuckle. The flowers have no odour; but for the beauty of their flowers, and their long continuance together, with their leaves being evergreen, they are preserved in most curious gardens. This is usually planted against walls and pales, to which their branches are trained; for they are too weak and rambling to be reduced to heads, and are liable to be killed in severe winter. Hence it ought to have a warm aspect, where it will begin to flower at the end of June, and there will be a succession of flowers till autumn. It may be trained like the other honeysuckles, and will flower among other shrubs in the south border of a plan-

tation, in a warm soil, till injured or killed by an unusually severe winter. It is propagated by laying down the young branches, which will easily take root; and may be afterwards treated like the common honeysuckles. See the first species.

4. *Lonicera Grata*; *Evergreen Honeysuckle*. Flowers in terminating whorls; leaves perennial, obovate, glaucous beneath, the upper ones connate, superfoliate; corollas ringent; colour of the flowers red outside, and yellow within; of a strong aromatic flavour.—Native of North America. This will not thrive where it is too much exposed to the cold in winter, but flourishes best in a soft sandy loam, and will retain its leaves in greater verdure in such ground than in a dry gravelly soil, where, in warm dry seasons, the leaves often shrink, and hang in a very disagreeable manner; nor will those sorts which naturally flower late in the autumn continue so long in beauty on a dry ground, unless the season should prove moist and cold, as those placed in a gentle loam.

5. *Lonicera Implexa*; *Minorca Honeysuckle*. Flowers ringent in whorls; bractes even; leaves perennial, smooth, oblong, the upper ones connate-perfoliate, the uppermost dilated.—Native of Minorca.

6. *Lonicera Periclymenum*; *Common Honeysuckle*. Flowers ringent, in terminating heads; leaves deciduous, all distinct. This species trails over bushes, and twines round the boughs of trees, with its very slender hairy or smooth branches; the corollas are usually red on the outside, and yellowish within, but they vary much in colour, between red, purple, and yellow, and are very pale in the shade. They are exceedingly sweet, especially in the evening. In climbing, it turns from east to west, with most of our other English climbers; and, in common with them, it bears clipping and pruning well. When placed near buildings, it is liable to be disfigured and injured by aphides, vulgarly called blights. These insects are not very numerous in spring; but as the summer advances, they increase in a surprising degree: their first attacks therefore should be watched, and the branches they first appear on cut off and destroyed; for when they have once gained ground, they are defended by their numbers. Small plants may be cleared from them by tobacco dust, or Spanish snuff; but this is not practicable for large trees. The leaves are likewise liable to be curled up, by a small caterpillar, which produces a beautiful little moth, *Phalaena Tortrix*. In the evening, some species of Sphinges or Hawk-moths, are frequently observed to hover over the blossoms, and with their long tongues to extract the honey from the very bottom of the flowers. A considerable quantity of nectareous juice may sometimes be discerned in the tube. Insects that are too large to penetrate into the narrow part of the tube, and have not a long tongue, like the Sphinges, to reach the juice, let it out by making a puncture towards the bottom, and so fairly tap the liquor.—There are several varieties: that called the Late Red Honeysuckle produces a greater quantity of flowers together than either the Italian or Dutch Honeysuckle; so that it makes a finer appearance than any of them during the time of flowering. There is also a variety with variegated leaves. The English call this plant Woodbine, Suckling, and Caprifoly, as well as Honeysuckle; the Germans, among a host of other names, call it *Speckhille*, *Geishlie*; the Dutch, *Gewoone Kamperfolie*; the Danes, *Gedeblad*; the Swedes, *Mattesblad*; the French, *Le Chevrefeuille des bois*; the Italians, *Caprifoglio* and *Vincibosco*; the Spaniards, *Madreselva*, *Virginia*, and *Periclimeno*; and the Portuguese, *Matrisylva do Norte*. For its medical uses, and method of propagation and culture, see the first species.

7. *Lonicera Japonica*; *Japanese Honeysuckle*. Flowers

terminating in pairs, sessile; all the leaves distinct; stem twining.—Native of Japan.

** *Chamaecerasa*—with two-flowered Peduncles.

8. *Lonicera Nigra*; *Black-berried Upright Honey suckle*. Peduncles two-flowered; berries distinct; leaves elliptic, quite entire; height three or four feet; corolla purple on the outside, white within, or quite white, pubescent. It flowers in March, April, and May.—Native of France, Switzerland, Austria, Silesia, and Piedmont.

9. *Lonicera Tartarica*; *Tartarian Upright Honeysuckle*. Peduncles two-flowered; berries distinct; leaves cordate, obtuse. This is a tree, often six feet high, rising with several trunks, frequently thicker than the wrist, spreading, branched very much from the bottom; corollas before they open parallel, club-shaped, of a deep rose-colour, when open flesh-coloured. In shady groves it varies with a white flower, and in autumn the leaves put off their fringes and become quite smooth.—Native of Russia, but not beyond lat. 55. N. It flowers in April, and the fruit is ripe in July. It is infested by the insect called *Meloe Vesicatoria*, and the insect is collected from this shrub for the apothecaries. The berries of this plant are eaten by the common people of Russia, though they are nauseously bitter, and purgative. The flowers have hardly any smell. The wood is very hard and solid, of a yellowish gray colour, beautifully veined, and used to make walking sticks, and the handles of tools.

10. *Lonicera Xylosteum*; *Fly Honeysuckle*. Peduncles two-flowered; berries distinct; leaves quite entire, pubescent. It rises with a strong woody stalk, six or eight feet high, covered with a whitish bark, dividing into many branches. The flowers come out on each side of the branches opposite, on slender peduncles, each sustaining two white flowers standing erect. Linneus says, that this shrub makes excellent hedges in a dry soil; that the parts between the joints of the shoots are used in Sweden for Tobacco pipes; and that the wood, being extremely hard, makes teeth for rakes. Gmelin says, that the Russians prepare an empyreumatic oil per descensum from the wood, which they recommend for cold tumors and chronical pains. Animals seldom touch the leaves. Birds eat the berries only in hard weather; they are reputed to be purgative and emetic.—It is common in the more northern parts of Russia, and in Siberia as far as the river Jenisea, and even in Hungary, the south of France, and Italy: Dr. Withering says it is a native of England. See the first species.

11. *Lonicera Pyrenaica*; *Pyrenean Upright Honeysuckle*. Peduncles two-flowered; berries distinct; leaves oblong, smooth.—Native of the Pyrenees, and of Siberia.

12. *Lonicera Alpigena*; *Red-berried Upright Honeysuckle*. Peduncles two-flowered; berries coadunate twin; leaves oval-lanceolate. This has a short, thick, woody stem, which divides into many strong woody branches, growing erect; flowers red on the outside, pale within.—Native of the south of Europe. See the first species.

13. *Lonicera Caucasia*. Peduncles two-flowered; berries coadunate-twin; leaves ovate-lanceolate, quite entire; height five feet; trunk covered with a whitish bark; branches spreading, red or hoary, testaceous; corolla irregular, red. The wood is hard, weighty, like ivory, beautifully veined with green, much esteemed for walking-sticks, which are sent to Petersburg. The Russians call it *Togustun*, and the Tartars *Tokus-tun*, which signifies nine-skins, because this shrub every year casts its epidermis, which adheres copiously to the twigs.—Native of Caucasus.

14. *Lonicera Cœrulea*; *Blue-berried Upright Honey-suckle*. Peduncles two-flowered; berries coadunate-globular; styles
